Abstract

This article reviews the history of financial crises on the basis of recent historiography on the subject. First, it presents the main definitions of crises, banking, debt, currency, and other forms such as inflation and sudden stops. Then after reviewing the issue of contagion it describes a general pattern of boom and bust, from the initial euphoria to the distress stage. The last section reviews historical examples with a particular focus on the frequency of different types of crises in advanced and emerging economies.

Introduction

Financial crises are an old problem. They range from debt and inflation crises in ancient Greece and Rome to banking, debt, and currency crises that have been affecting countries in modern times. Aside from the historical value of the study of past crises, it is the lessons that can be learned and applied to prevent the formation of credit bubbles and the handling of crises that makes the study of past crises an important subject for social scientists, practitioners of finance, and policymakers.

Before the collapse of Lehman Brothers in 2008 and the following financial crisis in the United States and other advanced economies there was a widespread belief that financial crises had become mainly an emerging economies' problem. Indeed, monetary authorities and financial institutions in advanced economies with the exception of Japan had managed to contain market disruptions that followed financial crises over the course of the 1990s and early 2000s. The Great Recession that followed the 2008 crisis quickly reversed this opinion and triggered a renewed interest in the causes, consequences, and policy responses to financial crises.

The study of financial crises also improves our understanding of credit markets and financial institutions at national and international levels. History shows that governments and credit institutions have responded to financial crises by rushing to design and create institutions, agencies, and new regulations during and in the aftermath of crises. Hence, learning from past blunders as much as from successful actions can improve the design of institutions, policies, and market regulations which in turn could reduce the incidence and virulence of financial crises. For instance, the Bank of England started to perform the role of lender of last resort, at least *de facto* if not *de jure*, during the South Sea bubble in the early 1720s and acted in that capacity to manage other crises onwards; the precursor of the New York Stock Exchange was established after a major financial crisis in 1792; the Federal Reserve (FED) was funded in part as a response to the Wall Street crisis of 1907; agencies such as the FDIC and major banking regulations such as the Glass–Steagall Act were introduced in the 1930s during the Great Depression; reforms of financial systems in countries such as South Korea, Mexico, and other emerging markets were introduced in the second half of the 1990s in response to financial crises in those countries and contributed to make their banking systems more resilient to financial shocks; and the financial crisis that followed the collapse of Lehman Brothers in 2008 forced the US congress and other governments in Europe to introduce sweeping reforms of domestic and international financial markets as well as banks to implement stricter risk management procedures.

Furthermore, the study of crises improves our understanding of the work of an economy, its structure, and responses to domestic and external shocks. Analyses of banking, currency, debt, and inflation crises have, among other things, enhanced our understanding of monetary circulation, the crucial role of interest rates, exchange rate regimes, and macro linkages and contributed to the development of models which in turn have influenced central banks and governments' policies – Irving Fisher, Milton Friedman, John Maynard Keynes, Paul Krugman, and John B. Taylor are famous examples. The existence of a correlation between quantity of money and price, the underpinning of what became known as the quantity theory of money, is for instance the result of a long genealogy of research, initially circumstantial and then more theoretical, on inflation crises caused first by debasement, then by increases in the supply of silver and gold, and eventually by the excessive printing of paper currency in fiat money monetary systems.

The vast literature on the subject ranges from historical overviews to analyses of financial crises caused by macroeconomic instability (including the mishandling of monetary, fiscal, and exchange rate policies) or works on disruptions of financial systems caused by the mismanagement of credit instruments, banks, and other financial institutions. The most influential contributions include a combination of these approaches, as, for instance, in the now classic Charles Kindleberger's *Manias, Panics, and Crashes: A History of Financial Crises (1978, and with Aliber 2011)* and the more recent Carmen Reinhart and Kenneth Rogoff's *This Time Is Different: Eight Centuries of Financial Folly* (2009). New contributions such as *Financial Crises: Causes, Consequences, and Policy Responses* (Claessens et al., 2014) provide an excellent overview of where we stand in terms of knowledge of determinants, management, impact, and lessons of financial crises.

The analysis of a financial crisis follows a typical scheme, like in a pathology report as well captured by Kindleberger's definition of 'anatomy' of a crisis. First, it looks at the causes of the boom and bust, the formation of a bubble whether it started in the stock market, banking, real estate, or other sectors of the economy. Second, it looks at the unfolding whether it is has been circumscribed to an institution, sector, or systemic, and what type of policy tools have been used – monetary, fiscal, exchange rate, and regulatory interventions. Third, it

gauges the impact and implications for the financial sector and for the overall economy, and whether the crisis has been circumscribed to the domestic economy or spread to foreign markets and institutions – international contagion. Measures of output losses, employment, private and public debt levels, number of bankruptcies, sector-specific indicators (e.g., number of foreclosures in the real estate sector), stock market indicators, and capital and trade flows are commonly used to determine the impact of a crisis, its magnitude, and length. Examples of these indicators and recovery time can be found in Reinhart and Rogoff (2009).

Financial crises can be identified by a series of typical features: unusual variation in the level of asset prices and the volume of credit; marked disruptions in credit markets (credit crunch); liquidity and solvency problems of large/systemic financial institutions; balance sheet problems of firms and households and of sovereigns (debt crisis); exceptional monetary authority's intervention to tackle liquidity and solvency problems; and exceptional fiscal measures to lessen the impact of economic downturns caused by a major crisis (Claessens and Kose, 2014).

Types of Financial Crises

There are different types of financial crises. The classical typology of crises encompasses banking, currency, and debt crises. Crises occurring simultaneously are labeled twin crises in the case of a combination of two crises (banking and currency, banking and sovereign debt, currency and sovereign debt) and triplet crisis when a country experiences banking, currency, and sovereign debt within a short period of time. Argentina, for instance, experienced a triplet crisis in 2001 when the country defaulted on its external obligations (debt crisis), abandoned its exchange rate peg to the US dollar (currency crisis), and experienced a banking crisis. In response to a series of capital account or balance of payments crises in emerging economies in the 1980s and 1990s, a further classification, 'sudden stop,' has been added to the traditional ones (Calvo et al., 2004; Edwards, 2004).

Within this widely accepted classification of financial crises, scholars have adopted ad hoc definitions in particular when constrained by data availability. In their work on the history of financial crises Reinhart and Rogoff (2009) differentiate crises on the basis of whether they can be defined by quantitative thresholds or by qualitative evidence. In the first group (quantitative) they include currency crashes, debasement, inflation, and sudden stop. A *currency crisis* entails a speculative attack on the exchange value of a currency which results in a devaluation/depreciation of the currency and disruption of external payments relations. Authorities could defend the currency by selling international reserves or using monetary tools such as raising interest rates to prevent capital outflow or legal barriers such as the imposition of capital controls (Claessens and Kose, 2014). Causes of currency crises include exchange rate misalignment, tension between domestic policies and the peg, and expectations based on balance of payments imbalances. The increase in the occurrence and incidence of these crises that followed the breakup of the Bretton Woods system of fixed exchange rate in the early 1970s stimulated new lines of research. Economists identified and grouped currency crises into three generation models. The first generation focuses on speculative attacks triggered by the anticipation of an imminent change in a country's exchange rate regime or parity. The second generation deals with the existence of multiple equilibria when investors attack a currency on the expectations that other market participants will do the same. Third-generation models look at how the realization of financial and corporate balance sheet mismatches leads to currency crises (Krugman, 1998; Claessens and Kose, 2014).

Debasement, an important category for scholars interested in the history of ancient and early modern crises when sovereigns used it as an easy and effective tool to raise revenues to finance wars and state expenditures, is a form of default on obligations as much as inflation, currency, and debt crises that have plagued emerging markets over the course of the last three decades. *Inflation* crises are defined by some authors as such when a country experiences an annual inflation rate of 20% or higher with extreme cases (mild and acute cases of hyperinflation) when inflation rate exceeds the 40% per year threshold (Reinhart and Rogoff, 2009). A *sudden stop* (also called balance of payments crisis) occurs when a country experiences a sudden reversal of capital inflows accompanied by a sharp rise in its credit spreads and followed by exchange rate depreciation, and (often) stock market declines. Emerging markets in Latin America and East Asia in the second half of the 1990s and Central and Eastern Europe after 2008 experienced a sudden reversal after having recorded large capital inflows in the years before the beginning of the crisis.

The second group contains banking crises, external and domestic debt crises. A *banking crisis* is defined on the basis of two distinct occurrences. In the first type bank runs mark the beginning of a crisis that leads to closure, merging, or takeover of one or more financial institutions. In the second type, no bank run marks the beginning of a crisis but the closure, merging, or takeover by public authorities of a systemically important financial institution leads to a similar outcome for other financial institutions. A banking crisis could become 'systemic' when it generates severe financial distress including disruptions in credit markets, domestic and/or international, and is followed by defaults in the corporate and financial sectors. Triggers of banking crises include runs on banks (frequent in the past before central banks became effective lender of last resort and the creation of insurance on deposits); abrupt correction in asset prices (frequent in the presence of asset bubbles); loss of confidence in the banking system (frequent in countries with weak banking systems as in emerging markets before the 1990s crises); poor supervision; and solvency problems in systemically relevant financial institutions (an extremely dangerous situation) (Reinhart and Rogoff, 2009; Laeven and Valencia, 2014).

A *debt crisis* takes place when a debtor, sovereign in the case of a state or private, is unable to service interest and principal as scheduled. Debt crises could end up in default and repudiation. A foreign debt crisis occurs when a government defaults on its own external or publicly guaranteed private-sector obligations held by foreign creditors and often denominated in foreign currency. Argentina's default on $95

billion in external debt in 2001 is an example of this type of default. Episodes of rescheduling in which governments repay their debt at less favorable terms than in the original loan are also classified as debt crises in several studies on the subject. Likewise in terms of domestic debt crises in addition to outright default it is now common practice to include episodes of debt restructuring. They include the freezing of bank deposits and conversions of deposits from foreign to local currency; the debasement or depreciation of the currency; strict regulations on capital movements; and preferential tax treatments for government debt among other forms of what is often referred to as financial repression (Reinhart and Rogoff, 2009, 2014).

Contagion

The study of financial crisis has increasingly focused on the contagion effect, on the channels of international transmission of a crisis (Neal and Weidenmier, 2003). Financial crises propagate across countries either when a crisis has a simultaneous impact on various economies or when it spreads from the initial center to other economies (Kindleberger and Aliber, 2011). Channels of transmission range from trade and capital flows, security and asset markets, to currency fluctuations and institutional features – links among banks and financial institutions of different countries, level of cooperation among monetary authorities, exchange rate regime.

The first type of contagion – simultaneous impact – generally occurs when a common shock such as sudden increases in commodity prices, international interest rates, or simultaneous collapse in housing prices in different countries ignites major financial distress and eventually economic crises in economies sharing common fundamentals. For instance, oil shocks of the 1970s and early 1980s had a negative impact on most advanced economies and non-oil-exporting developing countries; a sudden rise in international interest rates in the early 1980s triggered a debt crisis in highly indebted countries in Latin America; and a rapid decline in housing prices in the United States and other economies in 2007 and 2008 had dramatic consequences on the banking sector of countries with highly leveraged housing markets like the United States, the United Kingdom, Ireland, Iceland, and Spain.

The second type of contagion occurs when a domestic crisis spreads to other countries through cross-border linkages. For instance, the downfall of Lehman Brother in 2008 had a profound impact on foreign banks and financial systems exposed to the US subprime market (via mortgage-based securities and credit default swaps); or the exposure of German and French banks to EU peripheral nations' sovereign debt crisis has contributed to raise the threat of international contagion had one of the EU members defaulted. On the other hand, countries with less internationally integrated financial and banking sectors or closed economies have traditionally been less exposed to contagion. The soviet economy of the USSR, an autarkical system, was not affected by the Great Depression and indeed outperformed most Western economies in terms of economic growth throughout the 1930s. The fact that China, India, and Vietnam had rather closed domestic financial systems contributed among other factors to shield them from the East Asian financial crisis of the 1990s.

The two channels are not exclusive. The existence of both common fundamentals and cross-border linkages contributed to the spread of major crises around the world. The Great Depression affected the United States and European nations because of common domestic fundamentals – e.g., solvency of banks, the gold standard – as well as of macro linkages – e.g., integration of capital markets, geopolitical factors (the issue of Germany's war repayments), trade, and the gold standard adjustment mechanism. The East Asian crisis of the 1990s spread across countries with common fundamentals like overvalued currencies, real estate and equity bubbles, and weak credit markets. Macro linkages like rapid decline in capital inflows also contributed to exacerbate the impact of the crisis. The late 2000s crisis with "the bunching of banking crises and sovereign debt difficulties across countries" features both common shocks and cross-country linkages (Reinhart and Rogoff, 2011: p. 18).

In studying the international implications of crises, scholars have also identified two other important features of transmission on the basis of whether contagion takes place in a matter of hours or days, 'fast and furious,' or over time, 'slow-burn spillover' (Kaminsky et al., 2003). Fast and furious type of contagion tends to be characterized by an element of surprise (unanticipated shock) while the slow type by anticipated changes (e.g., an expected rise in interest rate). The country experiencing fast contagion features a rapid surge in capital inflows, with short-maturity debt. This is typical of countries running current account deficits and experiencing large capital inflows which in turn sustain credit and asset bubbles. Following the abrupt explosion of financial crisis countries in this category often experience a 'sudden stop' crisis, a quick reversal in capital flows with highly leveraged investors scrambling to exit the market. The existence of a common lender for countries exposed to the same crisis is worse in the case of unanticipated crisis since the lender has very little time to reduce or hedge its exposure (Reinhart and Rogoff, 2011).

Bubbles, Crises, and Financial Cycles

One of the most famous interpretations of the causes of financial crises goes back to the work of the Swedish economist Knut Wicksell at the end of the nineteenth century. According to Wicksell, a view later developed with different nuances by John Maynard Keynes, Joseph Schumpeter, and Irving Fisher and more recently by Hyman Minsky, crises are intrinsic to the financial cycle (or part of the financial cycle). In the first stage of a financial cycle, loose monetary policy contributes to expand credit and increase asset prices. The rise in asset prices will continue to the point of becoming a bubble when the level of price for that specific asset category is not justified by underlying fundamentals. The bubble eventually bursts and will be followed by a rapid decline in asset prices and in the case of major asset markets such as real estate by a recession. The depth and length of the recession will depend on the scale of the bubble and on the management of the fallout. Within this tradition,

Minsky developed one of the most convincing theoretical frameworks for understanding the recurrence of financial crises over time – the financial instability hypothesis. According to this hypothesis, financial systems are unstable, fragile, and prone to crisis because of the instability of the supply of credit. Charles Kindleberger using Minsky's framework shows, on the basis of a comprehensive analysis of historical accounts of crises from the seventeenth century onwards, how investors' irrational behavior, policy mismanagement, asymmetry of information, and the unreliability of credit systems have contributed to cycles of booms and busts. The financial instability hypothesis, according to Kindleberger "has great explanatory power for earlier crises in the United States and in Western Europe, for the asset price bubbles in Japan in the second half of the 1980s and in Thailand and Malaysia and the other countries in Southeast Asia in the mid-1990s, and for the bubble in US stocks, especially those traded on the NASDAQ, at the end of the 1990s" (Kindleberger and Aliber, 2011: p. 15).

The general pattern of a crisis identified by Minsky and Kindleberger can be dissected into five distinct stages of the financial cycle. It starts with a 'displacement,' when new technologies, financial innovations, new markets, or new policies create unusually profitable investment opportunities in a relevant sector of an economy or in a particular country or group of countries. The belief that expected profits will keep rising in that sector of the economy or country leads to rapid growth in the price of the underlying assets; this is the 'euphoria' or overtrading stage. Then first-time investors attracted by easy profits will get into the market: the 'mania' or bubble phase. Also, in this phase investors become more willing to take on debt because of the wealth effect and because, in several instances, the value of their collateral has risen – they become more leveraged. Market professionals and insiders realize that high prices of the assets are not justified by fundamentals and start selling those assets; the 'distress' stage. Finally, there is a 'revulsion' phase when asset prices fall; investors dump their shares, exiting the market of the distressed assets and any other market of similar assets (Kindleberger, 2011). On the latter issue, for example, when investors scrambled to exit the real estate market during the 2008–09 subprime mortgage crisis they also walked out of all sectors connected to it, including financial services. Or when Thailand and other East Asian countries experienced a major crisis in the second half of the 1990s, investors withdrew funds not only from those countries but from all emerging and developing markets. For stock markets, as remarked by Niall Ferguson, three further features can be added to this general pattern. The first occurs when insiders take advantage of the existence of asymmetric information – they use reserved information to cheat outsiders who do not have access to the same information. The second depends on the existence of cross-border capital flows: investors in more developed financial centers are better at timing the market before the burst of the bubble. The third is related to the existence of an easy credit environment. The availability of easy money increases the likelihood of a bubble. When markets are flooded with capital, investors chase high returns in riskier investments and financial firms become less diligent in risk assessment – it is a typical environment for moral hazard (Ferguson, 2008).

The three most studied bubbles and crashes of the early modern period – the Tulipmania in Holland (1634–37), the Mississippi and South Sea bubbles in France and Great Britain (1719–20) – featured the pattern described above. In all three cases a sharp increase in the price of particular assets in a short period of time – future contracts of tulip bulbs in Holland, state-backed securities in France, and trading of company shares and government debt in both France and England – was followed by an even faster contraction in price after the burst of the bubble. From a historical point of view it is worth noting how these episodes took place in two of the most advanced financial centers of the time – Amsterdam and London – and the largest continental economy – France. It shows how financial markets began to experience instability already in their infancy and at the same time that countries with a more developed financial system, such as Holland and England, fared much better than France, a country with a less sophisticated financial system and no lender of last resort. It was the swift action of a *de facto* lender of last resort, the Bank of England, the presence of an advanced financial sector, and the introduction of new regulations such as the Bubble Act of 1720 that enabled Great Britain to contain the negative spillover from the South Sea Company fiasco. (Atack and Neal, 2009; Garber, 2000).

A recent example of the different recovery time span experienced by countries affected by the same type of financial crisis can be found in the bubble in real estate and in stocks that occurred in Japan and Sweden in the second half of the 1980s. In both cases financial liberalization, easy credit, and inflow of capital lead to increases in consumption and to a lesser extent in investments. A boom in real housing prices and stock prices was followed by a sharp decline in both categories after the bubble bursts. The Swedish government nationalized the largest banks, created a good bank/bad bank to clean banks' balance sheets, and increased deposit insurance ceilings, all measures to prevent the collapse of the financial system and restore confidence in the banking sector. It also devaluated the currency by unpegging the Swedish krona from the European Monetary System. A sustained and lasting rebound of Sweden's economy began in 1994 only a few years after the burst of the bubble. Japan experienced a similar bubble buildup in the second half of the 1980s when both the stock market index, Nikkei, and land prices featured a threefold increase. Then at the beginning of the 1990s the situation reversed, the 'distress' and 'revulsion' phases indicated the burst of the bubble, stock and real estate prices sharply declined, and despite Japanese authorities' aggressive monetary policy and attempts to rescue the banking and insurance industries the country never fully recovered. Japan in contrast to Sweden failed to deal with the root causes of the banking and insurance sector problems. The legacy of this crisis has been that despite extremely accommodative monetary policy (interest rate at or close to the zero lower bound for a protracted period of time) Japan's annual rate of growth has been on average close to 1% throughout the 1990s and 2000s. Furthermore, large public deficits and accumulation of debt over the same time span contributed to bring the debt/GDP ratio above 200 percent, the highest level in the world.

Frequency

Financial crises of various types have erupted in most countries at least once over the course of the last five centuries. In some instances as isolated crises, in many other cases as part of waves of crises that affect regions – e.g., Latin America debt crisis in the 1980s or the East Asian Crisis of 1997 – or the world as in the case of the Great Depression in the 1930s and the Great Recession in 2008–12. The following list reflects the vast range of typology in terms of origin, time, and geographical coverage of the recent historiography of financial crises.

Time	*Name*	*Region*	*Main features*
1636	The Dutch tulip bubble	Holland	Speculation in future contract of tulip bulbs
1720	The South Sea bubble	Great Britain	Speculation in government debt;
1720	The Mississippi bubble	France	Speculation in government debt;
1792	Panic of 1792	The United States	Speculation in bank stocks and government debt;
1825	Latin American crisis	Latin America	Speculation on future growth of newly independent Latin American countries
1837	Cotton crisis	The United States	Fall in cotton prices, bubble in land prices, credit crunch
1857	Railroad crisis	The United States	Speculation in future earnings of railway companies
1873	Long depression	Europe and the United States	Depression in Europe after Franco-Prussian war; speculation in railway companies in the United States
1890	Baring crisis	Argentina and England	Speculation in Argentine securities
1907	Wall Street Panic	The United States	Speculation in trust companies shares
1929	1929 crash; Great Depression	The United States; world	Wall Street crash and beginning of the Great Depression
1970s	Oil crisis	Advanced economies	Collapse of the Bretton Woods system and oil crisis
1980s	Latin America debt crisis	Latin America	Surge in bank loans to Mexico and other Latin American countries in the 1970s and early 1980s
1987	Black Monday	The United States and world	Stock market crash
1991	Japan crisis	Japan	Bubble in real estate and stocks in 1985–89
1991	Scandinavian crisis	Finland, Norway, and Sweden	Bubble in real estate and stocks in 1985–89 followed by currency and banking crises
1994	Tequila crisis	Mexico	The surge in foreign investment in Mexico 1990–93
1997	Asian crisis	Thailand, Malaysia, Indonesia, South Korea, and other Asian countries	Bubble in real estate and stocks followed by currency and banking crises
2001	Argentina triple crisis	Argentina	Banking, currency, and debt crises
2001	Dotcom crash	The United States	Bubble in over-the-counter (OTC) telecom and internet stocks in the United States 1995–2000
2008	Subprime crisis	The United States	Bubble in housing market and mortgage backed securities
2009/13	Debt crisis	Europe	Debt crisis in several European Union member states

Rogoff, 2009. This Time is Different: Eight Centuries of Financial Folly. Princeton University Press, Princeton, NJ; Claessens, Stijn, Ayhan, Kose, Luc, Laeven, Fabian Valencia. (Eds.), 2014. Financial Crises: Causes, Consequences, and Policy Responses. International Monetary Fund, Washington, DC.

Frequency and severity of financial crises have increased over time (Bordo et al., 2001). History shows that all countries have been afflicted by different forms of crises during their emerging phase. Emerging markets whether in the nineteenth or late twentieth century (e.g., several countries in Asia, Latin America, Central and Eastern Europe) have experienced waves of financial crises (Bordo and Eichengreen, 2002). This is explained in part by the fact that they experience credit booms which in turn create bubbles in some sectors and by the increased exposure to the risk of international contagion via two main transmission channels, capital and trade flows. Furthermore, while emerging these countries are developing their own banking sector, financial markets, and institutions (including independent central banks) which once established tend to improve financial stability and capability to prevent and manage financial turbulences. The table below presents a stylized summary of the incidence of crises in advanced and emerging economies – emerging at the time under consideration – of sovereign debt, banking and inflation crises over the course of the last five centuries.

	Type of crisis		
Time	*Banking*	*External debt*	*Inflation*
1550s–1810s	Rare	Frequent in advanced economies of the time; serial in some cases, e.g., Spain and France	Rare
1820s–1850	Serial in advanced economies Rare in emerging markets of the time	Frequent in peripheral advanced economies and most emerging markets	Rare
1850s–1913	Serial in advanced economies Frequent in emerging markets	Frequent in peripheral advanced economies and most emerging markets	Rare
1913–45	Serial in advanced economies Frequent in emerging markets	Frequent in peripheral advanced economies and most emerging markets	Frequent in advanced economies and emerging markets
Bretton Woods period	Rare	Frequent in peripheral advanced economies and most emerging markets	Rare
1973–1980s	Frequent in advanced; serial in emerging	Serial in some emerging markets	Frequent in advanced; serial in emerging

These tables provide some clues to guide us through the maze of financial crises in a long-term perspective. In the first period, sixteenth to early nineteenth century, several European states (the advanced economies of the time) defaulted on their external debt – serial defaults in some cases like Spain (8 times), France (9 times), Prussia (3 times), and Austria-Hungary (5 times) (Reinhart and Rogoff, 2009). Occasional banking crises occurred in some European states but most of them were circumscribed to a few institutions. Bubbles were characterized by a major surge in the price of particular assets or financial flows (e.g., loans) but not all of them were followed by deep and long financial crises (Qian et al., 2010). Episodes of inflation during the early modern period were short lived and relatively low in comparison to those recorded during the interwar period and again after the collapse of Bretton Woods in the 1970s.

The period between the end of the Napoleonic Wars and the beginning of World War I featured a series of bubbles followed by stock market crashes, banking, and debt crises. The spread of the industrial revolution from England to continental Europe, the United States, and Japan followed by large surges in capital, trade, and migration flows had indeed contributed with ups and downs to the internationalization of the world economy. This process had been made possible among other things by the introduction and development of new credit instruments, banking activities, the adoption of the gold standard in almost all advanced economies, the increase in the speed of communication and information across the world, the rise of international financial centers, and readiness to move capital around the world (O'Rourke and Williamson, 1999). On the other hand, it also meant that economic problems and financial crises in one country could spread to other countries and regions. Hence, financial crises and bankruptcies that occurred in major financial centers of the time – London, Paris, Hamburg, and New York – were transmitted across the world affecting banks in other advanced economies and emerging markets. One of these crises which started in the United States in the fall of 1857 featured liquidity problems in New York which in turn affected London, Germany, and Latin America, and was analyzed by Walter Bagehot in his famous study, Lombard Street (1873). In his work, Bagehot formulated one of the most famous rules of central banks' intervention to provide credit to an illiquid bank. He wrote that a central bank in his role of lender of last resort should lend freely but at a penalty interest rate to prevent the liquidity problem from escalating into a solvency problem and in turn spreading to the banking system (Marichal, 2014; Kindleberger and Aliber, 2011).

The most famous of the late nineteenth-century international crises began in 1873 with stock market crashes and banking crises in Austria, Germany, and the United States and then spread to other countries in Europe, Latin America, and the Near East. Given its impact in terms of bankruptcies (mainly in advanced economies), debt crises (in emerging economies), and in terms of deep, widespread, and protracted economic recessions this crisis has been labeled as the first great depression. Other speculative manias in Paris, London, and New York ended up in banking crises in the 1880s and 1890s. Another crisis which started in Argentina in 1890 and involved one of the most famous London banks, Baring, had repercussions throughout other financial centers in Latin America, Lisbon, and Madrid (Mitchener and Weidenmier, 2008).

In terms of nineteenth-century debt crises, 'peripheral' nonindustrialized economies such as Spain, Portugal, and Greece in Europe; Egypt, Tunisia, and the Ottoman Empire in the Mediterranean region; and eight countries in Latin America defaulted on their debt – in some cases multiple times over the 1830–1913 period. Over the same period, improvements in the management of public finance together

with an increased availability of domestic capital enabled the largest advanced economies to avoid external default (Qian et al., 2010; Marichal, 2014).

At the beginning of the twentieth century the United States suffered one of the most damaging financial crises before the Great Depression. It started with a bank panic in New York in November 1907 and lasted more than a year. During that time, the stock market dropped 40% and almost 30 banks and 17 trust companies failed. The violent contraction felt throughout all sectors of the economy led to a severe depression in 1908. This crisis exposed the fragility of the financial system without an effective lender of last resort – it was indeed a group of financiers led by J.P. Morgan who intervened to prevent a complete collapse of Wall Street – and became a catalyst for establishing the Federal Reserve (1913) and the US banking system as it still operates today (Bruner and Carr, 2007).

The stock price bubble of 1927–29 in the United States which marked the beginning of the Great Depression had major domestic and international implications in terms of financial crises. Banking, debt, and currency crises became a worldwide phenomenon throughout the 1930s (Kindleberger, 1986; Temin, 1989; Bernanke, 2000; Eichengreen, 2008; Feinstein et al., 2008; Crafts and Fearon, 2010). The literature on the Great Depression is so extensive that it would require an entry in its own right. Among the numerous lessons from the 1930s, we recall how lack of cooperation among governments and their central banks generated further deflationary pressure on the world economy and exposed weak currencies to speculative attack. Central banks and governments believed in the monetary orthodoxy of the gold standard, which prevented countries from embarking on countercyclical policies (Temin, 1989; Eichengreen, 1995). Overall, the best solution for the world economy would have been a coordinated effort among countries to dismantle the gold standard in an ordinate manner. This did not happen, and countries that began to use exchange rate devaluation early in the decade together with other strategies such as expansionary policies (the United Kingdom, Sweden, and Japan), protection and import substitution (Brazil and Colombia), and capital controls and domestic expansion (Germany) outperformed those that abandoned the gold standard a few years later (the United States, France, and the Gold Bloc countries) (Feinstein et al., 2008).

During the period from the end of World War II until the early 1970s in part for the stability of the international monetary system banking crises were rather infrequent. After the collapse of Bretton Woods in the early 1970s the world economy entered an extremely unstable period during which both advanced and emerging economies experienced severe financial crises. The following figure based on Laeven and Valencia's (IMF) database provides an overview of the number of episodes by type of financial crises for the period 1970–2012. According to this set of data the world experienced 147 banking crises, 211 currency crises, and 67 sovereign debt crises. Several countries experienced overlapping crises which resulted in 41 twin crises – those involving currency crises (banking/currency and currency/debt) the most frequent – and 10 triplet crises (Laeven and Valencia, 2013, 2014).

Abstract

This article begins by defining some key concepts in financial regulation. It subsequently discusses the main objectives of financial regulation and supervision, as well as some of the most problematic issues in this area. After reviewing the main perspectives developed in the literature on this topic, the final part of the article outlines the main causes and consequences of the global financial crisis.

Introduction

The global financial crisis, which began in 2007 with the collapse of the US subprime mortgage market, delivered a major shock to the existing architecture for financial services regulation and supervision worldwide. It also brought into the spotlight the political salience of financial regulation, which has become a matter of great public interest, outside the restricted circle of policy makers, stakeholders, and experts involved.

The crisis highlighted the fact that policy failures in this sector directly affect the citizens in their position as bank account holders, small investors, insurance holders, pensioners, and so on. They are also indirectly affected as taxpayers, whenever the public authorities have to intervene to bail out or prop up ailing financial institutions, as happened during the financial crisis. Moreover, there is increasing public concern about the transparency and accountability of institutions and policy-making processes in this area.

This article begins by defining some key concepts, such as financial regulation, financial supervision, financial services, etc. It subsequently discusses the main objectives of financial regulation and supervision as well as some of the most problematic issues. After reviewing the main perspectives developed in the literature on this topic, the final part of the article outlines the main causes of the global financial crisis and the principal trends in the reform of financial regulation after the financial crisis.

Defining Key Concepts in Financial Regulation

'Financial regulation' concerns rule setting, that is, establishing the legal framework governing market entry and market activities in the financial sector. 'Financial supervision' concerns rule implementation, that is, the monitoring and the enforcement of regulation as well as the practical cooperation between supervisory authorities across borders and across various segments of the financial sector.

Two main types of regulation and supervision can be identified: 'prudential' and 'conduct of business.' Prudential regulation and supervision are concerned with ensuring the adherence of individual financial entities, such as banks, to prudential regulatory standards with a view to maintain financial stability. The economic literature generally distinguish between 'macro-' and 'micro'prudential regulation (Borio, 2011), which have two specific objectives, namely, macro- and microfinancial stabilities. Macrostability concerns the stability of the entire financial system and the stability of the key institutions and markets that are part of the financial system. Microstability concerns the stability (i.e., solvency) of intermediaries, viewed from the prospective of the users of the system. 'Conduct of business' regulation and supervision focuses on how financial firms conduct business with their customers. It deals with mandatory information disclosure, the integrity of firms and their employees, fair business practices, the marketing of financial products etc.

'Financial services' is a term used to refer to the services provided by the finance industry. A common classification of financial services includes banking, securities, and insurance. In the recent decades, market segmentation has tended to disappear, following a growing interpenetration between the various segments of the market. In other words, there has been an increasing blurring of boundaries between banking, securities, and insurance. Indeed, most of the main banks are financial conglomerates, which are financial institutions engaged in at least two of the following activities: banking, insurance, and securities trading. Nonetheless, the important difference across the main sectors remains and certain policy dynamics are sector specific.

'Financial integration' refers to the removal of barriers of various types to the free circulation of financial services. Often, this is accompanied by 'mutual recognition' of national legislation, which means that a country recognizes the regulations and administrative practices of other countries as equivalent to its own, thereby precluding the use of differences in national regulations to restrict access to domestic markets. It goes beyond the concept of 'national treatment' because countries agree to offer a treatment that is more favorable than national treatment to financial firms from other countries. A corollary of mutual recognition is 'home country control,' which means that financial supervision is carried out by the supervisory authorities of the country where a financial firm is headquartered. Unlike mutual recognition of national legislation, 'international harmonization' involves the approximation of regulation across jurisdictions through the deliberate creation of international standards. In the European Union, which is a regional jurisdiction, a distinction is often made between 'minimum harmonization' and 'maximum harmonization.'

Other concepts often used with reference to financial regulation are 'deregulation,' 'reregulation,' and 'liberalization.'

Deregulation means the downsizing or the elimination of public authorities' rules, reducing their control in the economy, in this case in the financial sector. Reregulation means the reformulation of old rules and the introduction of new rules. Reregulation can be procompetitive, with emphasis on liberalization, or it can place emphasis on complementing the liberalization process. Liberalization means the injection of more competition in the economy, in this case the financial sector.

The Objectives and Rationales of Financial Regulation

The main objectives of financial regulation are (1) to safeguard systemic stability, (2) to maintain the safety and soundness of financial institutions, (3) to protect consumers, and (4) to promote competition and efficiency. Internationally, regulation can also constitute a means of trade protectionism by exploiting specific comparative advantages and reducing adjustment costs to the new rules set in place. Indeed, the content of regulation can produce different adjustment costs for different countries and financial operators, substantially affecting their competitiveness, as discussed below.

There are three main rationales for financial regulation, which to a large extent mirror the objectives listed above: (1) to prevent potential systemic problems related to negative externalities, (2) to correct market imperfections and failures, and (3) to reduce moral hazard related to safety next arrangements, such as lender of last resort and deposit protection schemes.

The first rationale for financial regulation is to deal with systemic risks and negative externalities (Davies and Green, 2008). Certain financial institutions, first and foremost banks, have a pivotal role in the financial system and their failures can cause systemic problems. Banks are highly interconnected to other financial institutions, not only other banks (e.g., in their gross positions with each other in clearing systems and in interbank deposits), but also insurance companies and securities firms. Furthermore, many banks are financial conglomerates that combine under one roof banking activities, securities trading, and insurance. Banks also perform a crucial role in payment systems, which are vital for the activities of nonfinancial firms as well as the wider public.

The special tasks performed by banks mean that there are several externalities to be considered in regulating finance, especially in the banking sector. The failure of a bank can directly cause losses to other interconnected banks within and across borders. It can also cause a gridlock in payment systems. Finally, bank runs may have contagious systemic effects because of information symmetries. In the absence of reliable information, depositors have an incentive to withdraw their deposits from a bank facing (or allegedly facing) solvency problems. This turns into a self-fulfilling prophecy, which may have contagious effects, spreading to other banks.

The second rational for financial regulation is to protect consumers, correcting market imperfections or market failures that would compromise consumer welfare in a regulation-free environment. Market imperfections and failures stem from the fact that consumers are not in a position to make informed decisions about the security of their banks: they lack relevant information, they do not have the ability to assess the information available, and the transactions costs involved in doing so are high (Llewellyn, 1999).

The third rational for financial regulation is to deal with the moral hazard associated with safety-net arrangements, such as lender of last resort and deposit insurance, which are set in place by the public authorities. The lender of last resort function is performed by central banks that have the authority and financial resources to act as the ultimate source of credit (Goodhart, 1999). In emergency situations, central banks extend their loans to solvent but illiquid financial institutions, often to avoid a run on the banks accompanied by financial panic. Deposit insurance is a formal scheme normally established by law that is designed to limit the losses of depositors in the event of banks failures.

These safety net arrangements pose four potential moral hazards. First, consumers may be less careful in the selection of banks and may even seek high-risk institutions that offer high interest rates on the grounds that if the bank fails, they will receive compensation. Second, the financial firm may be induced to take more risk because depositors are protected in the event that the institution fails. Third, risk is subsidized because depositors do not demand an appropriate risk premium in their deposit interest rates, and financial counterparties are not careful in pricing in risk in their financial interactions with other financial institutions (Llewellyn, 1999). In this scenario, banks adapt their strategies to maximize expected profits.

The Main Open Issues in Financial Regulation

Financial regulation raises a variety of public policy issues (for an in depth discussion see Brunnermeier et al., 2009). Some of them are common to all types of regulation, others are specific to the financial sector. The first issue is the need to balance the costs and benefits of regulation, so as to prevent 'regulatory arbitrage' across jurisdictions, which takes place when financial operators and their activities move toward jurisdictions that regulate them less tightly. Financial services are inherently borderless activities: they can move relatively easily across borders, hence countries have an incentive not to regulate them too tightly. Yet, policy failures in this area can be costly and can cause substantial negative externalities because financial instability does not stop at national borders (Herring and Litan, 1994).

Therefore, effective financial regulation requires to some extent harmonized rules across jurisdictions to prevent regulatory gaps and arbitrage. International regulatory harmonization has transaction costs when it is negotiated and it has implementation costs when domestic rules are changed to comply with either international rules or rules from third countries (Simmons, 2001). All this raises the problem of the underprovision of the public (or 'semipublic') good of financial stability, meaning that everybody benefits from financial stability, but the costs of providing this public good tend to be specific (Schinasi, 2006).

The second issue in financial regulation concerns the potential for 'regulatory capture,' meaning that the financial industry or part of it can have overwhelming influence in the shaping of regulation and the carrying out of supervision by the

competent authorities. The financial industry has powerful resources at its disposal, such as expertise and technical knowledge; human resources, engaged in lobbying activities; financial resources, often deployed to exert influence in policy making (Baker, 2010). Financial actors, especially the main transnational players, are often well-organized lobbyists active at the national and international levels. Prior to the financial crisis, the augmented complexity of governance in this area had led to an increased reliance on the private sector for the provision of information and expertise, the issuing of private (soft) regulation, and the self-monitoring and self-enforcement of agreed norms, at least for some financial activities or entities, such as hedge funds and rating agencies (Porter, 2005). The crisis partly reversed this trend (at the least in the short and medium term), as explained in the penultimate section.

Third, there is a disjuncture between globalized financial markets and national systems of supervision (Padoa-Schioppa, 2004). This fragmentation of powers and responsibilities severely constrains the public authorities' ability to regulate and supervise financial markets and financial entities active in their jurisdictions. A specific problem is posed by ailing cross-border financial institutions. To begin with, there is the distribution of burden sharing (i.e., the costs of rescue plans) between the home and host countries and across the several host jurisdictions in which cross-border financial institutions operate. Furthermore, sometimes financial institutions are too big to be rescued by their home countries (ultimately by the treasury and taxpayers of the country in which they are headquartered).

The fourth problematic issue in financial regulation concerns the separation of central banking functions from supervisory functions (e.g., Goodhart and Schoenmaker, 1995; Oosterloo and de Haan, 2004). This in turn raises the issue of which authorities should be responsible for macrostability (i.e., stability of the system), microstability (solvency of individual financial entities), and consumers protection. It also feeds into the ongoing debate concerning the 'best' model for financial supervision, whereby the main choice is between the establishment of single financial services authorities responsible for the oversight of all financial services and the allocation of supervisory functions to a variety of sectoral authorities. Worldwide there are different national models in place concerning the institutional arrangements for financial supervision (Masciandaro and Quintyn, 2007; Masciandaro, 2005). Several countries had reformed their domestic frameworks for financial supervision in the decade prior to the crisis, and changed it again in light of the crisis.

Fifth, the global financial crisis brought into sharp relief the interconnection between monetary policy, macroeconomic imbalances, and financial stability, in particular the effects that the former can have on the latter, as explained in the penultimate section.

Perspectives on Financial Regulation in the Academic Literature

The literature on financial regulation has been developed from a variety of disciplinary perspectives: law, economics, and political science. Of particular interest is the latter, which has focused on the public policy aspects of financial regulation. Broadly, three or four main bodies of scholarly works can be identified, which tend to focus their analysis at different levels of governance.

First, there is the international political economy literature on international financial regulatory harmonization and cooperation. The assumption is that international regulatory harmonization and cooperation benefits some countries more than others, affecting the competitiveness of national firms. Consequently, international harmonization and cooperation will take place only when they are in line with the preferences of the main jurisdictions (Drezner, 2008), which in the past was the United States because of the size of its domestic market. Recently, international political economy scholars have considered the European Union as an increasingly influential actor in the making of rules for global finance because of the sheer size of its internal market. In this literature, national policy makers' preferences are shaped by concerns for the competitiveness of national banks in international markets, and by the need to ensure financial stability domestically (Singer, 2007). According to this 'regulatory arbitrage' explanation, national policy makers seek to set in place at the international level rules that would promote financial stability, without creating serious competitive disadvantages to their national financial industry.

A second stream of literature focuses on the pervasive power of banks, which are influential lobbyists with plenty of financial, human, and technical resources at their disposal (Baker, 2010; Underhill et al., 2010). Hence, big banks are those most likely to yield influence in the making of financial regulation: they can lobby directly at the international level, and/or their national policy makers. The 'bank power' explanation argues that the most influential players whose preferences prevail in shaping international and domestic financial rules are the main stakeholders in the financial industry. It links to the economics literature on regulatory capture, which posits that financial regulators are captured by the industry they are supposed to regulate.

A third stream of literature argues that financial governance arrangements fall within the responsibility of a transnational policy community of experts actors (Kapstein, 1992; Porter, 2005). These actors have common professional and educational backgrounds and share similar epistemological views. The argument is that small groupings of experts facilitate information exchange and processes of deliberation. In this context, actors develop homogenous preferences and share common views on what problems need solutions and with what instruments. Over the 1980s and 1990s, a dominating paradigm for financial services regulation emerged internationally and in the main jurisdictions, including Europe. It has been referred as the 'neoliberal' paradigm (Gamble, 2009) or as a 'governance light' approach, which favored 'market-based governance,' based on a benign view of financial markets and grounded in efficient market theories (Underhill et al., 2010: 10). This regulatory paradigm was sponsored by the United States and the United Kingdom, which prior to the crisis exercised considerable influence in international regulatory fora.

The literature on varieties of capitalism (for a review, see Jackson and Deeg, 2008) has examined the main components of varieties of capitalism, namely, industrial relations

institutions; education and training systems; corporate governance and systems of corporate financing; product markets; social protection systems and welfare states; and public intervention in the economy. The financial system has also been considered a component of the variety of capitalism, but attention has centered on sources of corporate finance (Zysman, 1983; Deeg, 2010). A literature on national varieties of financial capitalism as such is largely missing. However, some works rooted in comparative political economy and inspired by historical institutionalism have examined how the configuration of national financial system (Allen and Gale, 2000; Rajan and Zingales, 2003) and domestic regulatory institutions affect the preferences of policy makers on financial regulation domestically and internationally (Fioretos, 2010; Posner, 2010).

Finally, there is a set of works that focus on national supervisory arrangements, analyzing different models of supervision with a view to assess which works best (Masciandaro and Quintyn, 2007; Masciandaro, 2005; Oosterloo and de Haan, 2004). Some economists and political economists who in the past had worked on indicators of central bank independence and its relation to national macroeconomic performances, first and foremost, inflation, have extended this kind of analysis to financial supervisory authorities. However, unlike in the case of central banks, there seems to be no 'winning' or 'best' model of financial supervision. Other economists have tried to identify to measure the stringency (or otherwise) of financial regulation across countries with a view to determine what type of regulation works best, using various indicators (Barth et al., 2006).

The Main Causes of the Global Financial Crisis

The financial industry expanded substantially over the last decades. In 2011, banking assets in the United States were $12 441 (data from the US Federal Reserve), in the European Union they totaled €35 901, distributed as follows: Germany €7995, France €6674, and the United Kingdom €11 142 (data from the European Central Bank). Securities trading including derivatives in the United States was $849 791 billion, in the European Union it was €655 259 billion (data from the World Federation of Exchanges). Securities trading, excluding derivatives, in the United States was $39 225 billion, in the European Union was €35 701 billion, distributed as follows: Germany €1302 billion, France €928 billion, and the United Kingdom €7711 billion (data from the ECB). Insurance premia in the United States totaled $2154 billion, in the European Union they were €1072 billion, distributed as follows: Germany €178 billion, France €190 billion, and the United Kingdom €206 billion.

The global financial crisis that began in late 2007 and reached its peak in the autumn of 2008 had three main interrelated causes, namely, a relatively loose monetary policy, international macroeconomic imbalances, and financial regulation that was not fit for purpose. The building up to the crisis took place in an international context of relatively loose monetary policy, especially in the United States and Europe, where central banks mainly focused on keeping inflation under control (which they did) without paying sufficient attention to other economic indicators, such as external and internal imbalances (such as property bubble or consumers indebtedness). It was a period of 'irrational exuberance.'

International macroeconomic imbalances were caused by increasing surpluses in the balance of payments of many Asian economies and the persistent deficit of the US balance of payments, compensated by capital inflows into the United States from surplus economies. Substantial macroeconomic imbalances existed also within the European Union. Capital inflows from Asian economies and from surplus to deficit countries in the European Union were mainly intermediated by the banking system. They contributed to the availability of credit, which fueled, for example, real estate bubbles and facilitated a loose monetary policy.

Financial regulation created the wrong incentive structures and promoted moral hazard. It facilitated excessive leverage by banks and the growth of a 'shadow' unregulated banking sector linked to regulated banks. Other activities, such as rating agencies, hedge funds, and over-the-counter derivatives were mainly subject to industry self-regulation that was not fit for purpose. For example, credit rating agencies were far too generous in their ratings of structured financial products.

The crisis started off as an 'old fashioned bubble' in the United States and spread quickly worldwide, first and foremost to the United Kingdom, whose financial industry is highly interconnected to that of the United States. Subsequently, the financial crisis hit the real economy because banks began to deleverage, cutting credit to industry and services, with direct negative effects on economic growth and employment. Moreover, in several countries, such as the United Kingdom and Germany, the state had to intervene to recapitalize banks. In some cases, such as Ireland and Spain, the huge losses incurred by banks and taken over by the state threatened the very solvency of the state, triggering a sovereign debt crisis. In other countries, such as Greece and Portugal, the sovereign debt crisis began as a traditional fiscal crisis, due to persistent fiscal imbalances between revenues and expenses and, consequently, the building of the public debt.

All these countries at the periphery of Europe were also affected by external and internal imbalances, and eventually had to resort to external financial support from the European Union in some cases from the International Monetary Fund to stave off the sovereign debt crisis. In turn, the sovereign debt crisis risked turning into a banking crisis, showing the interconnection between the two types of crises in certain countries, such as Greece and Italy, whose (rather 'traditional') banking system had coped rather well with the global financial crisis of 2007–08. However, once the Greek and Italian states faced default, their banking systems were penalized and the sovereign debt crisis risked turning into a banking crisis.

The Regulatory Response to the Global Financial Crisis

In the aftermath of the crisis, several jurisdictions revised their framework for financial regulation and supervision. Although the measures adopted are specific to each jurisdiction, three general trends can be detected. First, the reforms enacted should be seen as incremental changes tinkering with the

existing regulatory framework, rather than path-breaking reforms changing the fundamentals of the system. For example, the main regulatory measures that focused on banks, the so-called Basel III Accord (2010), negotiated by the Basel Committee on Banking Supervision and eventually endorsed by the G20, build on an existing set of rules, the Basel II Accord, rather than reinventing them altogether. These international standards are in the process of being implemented domestically in the jurisdictions that signed the accord.

Second, the vast majority of the measures adopted regulated activities or financial institutions that were previously not subject to public regulation, such as over-the-counter derivatives, or were subject to industry self-regulation. In other instances, they imposed heavier, more prescriptive, and more burdensome requirements on financial entities that were already regulated prior to the crisis, as in the case of higher capital requirements and new liquidity management rules for banks. For example, the European Union issued new (legally binding) rules on rating agencies, alternative investment funds managers, over-the-counter derivatives, etc. Analog measures were taken in the United States with the Dodd-Frank Wall Street Reform and Consumer Protection Act of 2010, which increased the power of financial regulatory agencies, reduced regulatory gaps, and consolidated the regulation of systemically important institutions.

Third, the global financial crisis drew attention to macroprudential supervision (also referred to as systemic supervision) designed to safeguard the stability of the entire financial system and the interconnection between micro- and macrofinancial supervision. Prior to the crisis, the attention had very much focused on microprudential supervision designed to maintain the solvency of individual financial institutions. The global financial crisis demonstrated that this narrow focus was not enough to ensure financial stability. It also emphasized the need to adequately regulate and supervise all systemic institutions, that is, the financial institutions whose failure might endanger the stability of the system. In the aftermath of the crisis, several jurisdictions set up new supervisory bodies to deal with microprudential risk. For example, the European Union established the European Systemic Risk Board, its chair to be elected by and from the members of the General Council of the European Central Bank and in charge of monitoring macroprudential risk.

Finally, prior to the crisis, financial regulation was mainly a 'technical' policy area in which there was a very limited involvement of politicians and that was of marginal interest to the wider public. It was, however, an arena where the interests of the financial industry played out. After the crisis, heads of state and government, such as Barack Obama, Nicolas Sarkozy, and Angela Merkel, became interested in financial regulation, at times adopting populist stances to appease public opinion.

Conclusion

Financial regulation has become a matter of great public interest after the financial crisis, though it has always been a key (but rather 'technical') public policy. It pursues a variety of objectives, the most important of which is to preserve financial stability. The global financial crisis highlighted some problematic issue, which have only partly been addressed by the regulatory reforms that followed the crisis. Among the main open issues, there are the disjuncture between globalized markets and national supervision; the problem of ailing cross-border financial institutions or of financial institutions too big to fail; and the link between the financial crisis and the sovereign debt crisis, which have been left unaddressed, both internationally and at the national level. Financial regulation is therefore not well equipped to prevent or deal with the next financial crisis.

Fire, Human Use, and Consequences

Abstract

The ability to handle fire and exploit fuel is, like language and the use of tools, a universal human attainment: no human society in historical times is known to have lived without it. In addition, the ability to handle fire and exploit fuel is also exclusively human; while other animals have developed rudimentary signals and tools, only humans have learned to handle fire. Today fire is continuously present in all human societies. It is used in many different guises, some highly visible, others largely hidden from public view and consciousness. Access to, and control over, fire and fuel have played an important part in human history and social evolution, more important than is generally acknowledged in the literature of the social sciences.

Introduction

The ability to handle fire and exploit fuel is, like language and the use of tools, a universal human attainment: no human society in historical times is known to have lived without it. In addition, the ability to handle fire and exploit fuel is also exclusively human; while other animals have developed rudimentary signals and tools, only humans have learned to handle fire. Today fire is continuously present in all human societies. It is used in many different guises, some highly visible, others largely hidden from public view and consciousness. Access to, and control over fire, and fuel have played an important part in human history and social evolution, more important than is generally acknowledged in the literature of the social sciences.

The Original Domestication of Fire

Fire is, according to dictionary definitions, a process of combustion, manifested by heat and light. It occurs relatively rarely in nature; when it does, it does not last long, with a few exceptions such as the burning coal-fields in Northern China, which have been alight for many centuries. Most natural fires have rapid and drastic effects. They cause a quick disintegration of organic matter, reducing it to ash and smoke in a process of transformation that is almost the prototype of 'destruction.'

During the Paleolithic, human groups have learned to turn this destructive and essentially aimless natural force into a regularly available asset that could be made useful for a variety of 'productive' purposes. When and how exactly this transition occurred is still unknown (cf Stringer, 2011). It stands to reason to assume that the actual 'domestication' of fire was preceded by a prolonged phase of 'association' with fire (Burton, 2009), when groups of hominins gradually familiarized themselves with the presence of fire and learned the trick of keeping it burning by 'feeding' it with fuel. The domestication of fire was not a single event, but a series of incidents, endeavors, failures, and occasional successes, resulting eventually in the unique bond of humans and fire.

The key toward understanding the importance of this bond is fuel. All animals derive practically all of their energy from one single source – food, either in the form of vegetation or, in the case of predators, of other animals. Humans alone have added fuel to food as a second major source of energy. Originally, of course, fuel is also derived from plant vegetation; but whereas food is almost always consumed while it is still 'fresh,' in the sense of being still alive or almost alive, the matter that is used as fuel is usually dead, and has been dead for some time. It can serve as a source of energy because it still contains vegetable matter and thus preserves solar energy, which is as it were locked up in the dead organic matter and can be released by burning.

Of course, none of these ideas about the transformations of energy were known to our early ancestors. Still, the very process of domesticating fire is likely to have stimulated the further development of their general capacity for culture – for learning new forms of behavior, sharing those with others, and transmitting them to following generations. Adjusting their behavior in such a way that a fire could be kept burning continuously, they generated the uniquely human 'fire regime,' which enabled them to expand their control over their natural environment, while at the same time affecting their own social arrangements and their personal habits and feelings (cf Goudsblom, 1992: pp. 12–41). Fire thus became a part of the 'anthroposphere'; and most of the fires burning on the earth today are 'anthropogenetic' (De Vries and Goudsblom, 2002).

The uses of fire were diverse, ranging from the enjoyment of heat and light to clearing land for hunting and gathering and to cooking (Wrangham, 2009). Their overall tendency was to make life in human groups more secure and comfortable but, by implication, also more vulnerable and dangerous. Fire increased people's productive as well as their destructive potential. Its control thus reinforced a basic trend in human history and social evolution: *the increasing differentiation in behavior and power between humans and all biologically related species*.

Fire and Agrarianization

Toward the end of the Paleolithic, between 15 000 and 10 000 years ago, some human groups began to extend their care and control over selected plants and animals. This, the rise and spread of agrarian production, may be called 'agrarianization,' just as 'industrialization' is used to refer the subsequent rise and spread of industrial production in the modern era.

Agrarianization was not, as is sometimes assumed, the first, but the second great ecological transformation brought about by humans. That transformation could not have taken place without the firmly established control over fire. Once it was under way, it in turn deeply affected the further development of the part played by fire in human society.

The domestication of fire was a precondition for agrarianization first of all, because in most areas using fire ('slash and burn') was the most efficient technique of opening up fields for cultivation by removing the existing vegetation. Moreover, most of the crops selected for cultivation needed cooking before consumption as a staple food. As a further, less tangible precondition, the solidly established 'species monopoly' over fire gave humans a dominance over other animals, which enabled them not only to bring certain species under direct control but also helped to keep most of the remaining 'wild' animals at a distance from their crops and herds. Finally, the long-standing familiarity with a fire regime probably helped to prepare people for the strains of an agrarian regime demanding self-imposed 'deferred gratification.'

With agriculture and livestock, fire was no longer the only nonhuman source of energy under human control. Gradually it ceased to be the prominent focus of group life that it had been for many thousands of generations, becoming increasingly more dispersed over various sorts of specific 'containers,' such as hearths, ovens, and lamps, beyond which it was not allowed to spread. Its use was subjected to stricter regulation. Whereas during the initial stages of domestication, the main concern had been to keep the one fire burning, the main concern now became to prevent the many fires from causing a conflagration.

As the more advanced agrarian societies grew more populous, the number of fires in use increased proportionally. Those fires were increasingly concentrated within the 'fire-protected zones' of towns and villages, in special containers. The uses of fire became more specialized, with various crafts and professions such as smiths and potters developing their own pyrotechnic skills. With proliferation, concentration, and specialization came new forms of organization, if only to meet the growing need for fuel. Unavoidably, the use of fire also reflected the process of stratification, as some members of privileged groups came to command huge supplies of fuel, and could use fire for impressive displays of power, whereas many poor people might never call any fire their own.

A common problem in all advanced agrarian societies was the prevention of uncontrolled fire in cities. For the growing urban populations the proliferation of fires increased the risks of blazes, while the accumulation of property meant that people had more to lose. Of course, it was fire as a natural force with its capricious and self-generating destructiveness that was feared. In case of a military raid people had to reckon with the common practice of 'sack and burn.' Sometimes a rural region might be caught in a vicious circle of mutual arson (cf Frierson, 2002). But peasants and farmers ordinarily encountered fire only in its domesticated settings, where the greatest danger lay in carelessness and where they had to rely on their own and their neighbors' incessant caution.

In preindustrial towns, there was little one could do once a fire broke out. Usually the only way of stopping it was by creating a 'fire break' and tearing down the buildings toward which the fire was advancing; deliberate destruction by human hands had to put an end to the blind destruction by fire. By far the most effective way of restricting the risk of conflagrations was then, as it still is, prevention (cf Bankoff et al., 2012).

Today we are perhaps inclined to conceive of problems of fire prevention primarily in terms of technology: building materials and technical equipment. However, the problems have always been at least as much civilizational. The crucial issue was human behavior in its social context of informal and formal controls; of habits and regulations.

Little is known about the organization of fire brigades in preindustrial cities. The available evidence suggests that their effectiveness, and their very presence or absence, reflected important aspects of the social structure. In ancient Rome, fire brigades at first operated as private bands, and were later brought under imperial military command. A glimpse of the situation in the Roman provinces is shown in a letter from the emperor Trajan, written in 112 CE, in which he refused permission to the governor of Nicomedia to establish a fire brigade of citizens on the grounds that such an organization could easily "turn into a political club" (Mann, 1986: p. 324). One of the great social innovations in the towns of medieval Europe was that they had civil fire brigades.

Fire in Industrial Society

After the original domestication of fire and the rise of agriculture and animal husbandry, industrialization was the third major ecological transformation set in motion by humans. Once more, natural forces originally outside the human realm were brought under human control. The forces that now began to be exploited were sources of energy that, in their practical applications, were radically new, but as to their origins extremely old. They consisted of large, untapped sources of solar energy stored up in dead organic matter that, in secular geological processes, had been accumulated and transformed into various kinds of fuel. When, around 1750, means were invented to exploit these energy sources with the aid of steam power and other technological innovations, humankind entered, in the words of the environmental historian Rolf Peter Sieferle (2001), a 'subterranean forest' of huge dimensions that, in the course of time, turned out far to exceed the initial expectations. The successful tapping of the enormous supplies of coal, and later also of oil and gas, had the additional advantage of greatly facilitating human access to a great variety of other mineral resources, from iron to plutonium.

From the start, industrialization had contradictory and seemingly paradoxical effects. Being essentially a fuel revolution, it led to an enormous increase in the number, variety, and intensity of artificial fires. Just as the first stages of agrarianization were marked by extensive and conspicuous use of fire in the clearing of land by slash and burn, early industrialization dotted the landscape with smoke stacks and clouds of steam. In the development of agriculture, the extensive use of fire gradually made way to more intensive forms of tillage with less conspicuous use of fire. Something similar happened in the process of industrialization. As technology developed, fire and fuel became increasingly indispensible to maintain the rising standards of living, while at the same time, as part of the same process, their presence was made less cumbersome. Fire was

kept at bay as much as possible, out of hearing, seeing, or smelling distance.

Consequently, in highly industrialized societies, the fire and smoke involved in industrial production are now mostly, in the image of Norbert Elias (2012), 'hidden behind the scenes' of public as well as private life. Electricity in particular has helped to create the illusion that modern comfort and luxury can be provided without fire and fuel; it is too easily forgotten that most electricity (like applicable nuclear energy) is itself generated by the combustion of fossil fuels. In spite of appearances, industrial as well as agricultural production continue to be highly fuel intensive.

The same is true of transportation. Typical products of modern fuel-intensive industry are cars, with engines designed to be propelled by finely tuned and minutely controllable combustion processes. Cars are made of steel, plastic, and glass – materials produced and processed at great heat. Yet when we get into our vehicles and turn on the electrical ignition to start the engine we are usually hardly aware of using fire and the products of fire. Nor are most of us continuously alert to the fact that by driving we are producing CO_2 emissions that may be contributing to global warming.

The fuel-intensive character of modern technology is matched by advanced standards of fire prevention. Every branch of industrial production, from the building trade to the manufacture of clothes and furniture, is subject to strict measures with respect to fire. In such branches as the aircraft or the hotel industry, regulation has become international. Fire prevention is thus contributing to worldwide standardization in architecture and building.

The continuing growth in the sheer quantity of available energy has led to an enormous increase not only in productivity but also in the social potential to destroy, in 'destructivity.' Just as the means of preventing and fighting fires became more effective, so did the means of starting fires. In the agrarian era, walled cities were relatively safe havens of protection from military attacks. In the twentieth century, by contrast, cities have not only increased in numbers and size, they have also become easy targets for military arson from the air. The bombings of World War II caused some of the largest urban fires in history, as in Hamburg, Dresden, and Tokyo; even after the droppings of the atomic bombs on Hiroshima and Nagasaki, most casualties and the worst material damage were caused by the subsequent firestorms (cf Eden, 2004).

The comforts and discomforts of fire are distributed over the world population in a way that directly reflects the stratification in terms of wealth and power. In large parts of Asia and Africa there is a pressing shortage of firewood; by cutting down trees for fuel, poor country folk play a part in worldwide deforestation. At the same time, in many regions, from Indonesia to Latin America, large tracts of forest are burnt down in order to clear land for growing crops that can be used as food or, ironically, fuel. These contradictory practices have the similar effect of furthering deforestation (cf Pyne, 2001).

Worldwide inequality is also reflected in the uneven exposure to blazes. An increasingly large portion of the world population is now living in slums in the mega-cities of 'the developing world.' In densely crowded areas that are almost inaccessible to fire-fighting vehicles, the combination of inflammable dwellings and dependence upon open fires for heat and cooking serves as "a superlative recipe for spontaneous combustion" (Davis, 2006: p. 127). Fires break out so often that they only reach the international press if the number of casualties is written in at least three digits.

Fossil fuels rank today among the world's most highly valued natural resources and economic commodities. They form a major item in international trade, both in actual material exchange and in the virtual world of speculative 'international markets.' Some of the main loci of extraction are among the world's most violently contested areas, where large international companies are tense relations with each other as well as with the local population and the states that claim sovereignty over the territories from where the fuels are extracted. Some of the world's most volatile hot spots are in areas rich in fossil fuels, first of all the Middle East, but also such countries as Libya, Nigeria, Venezuela, and Azerbaidzhan. Pipelines and shipping routes to and from these centers are equally subject to geopolitical pressures. All this turmoil is accompanied by rising concerns over ecological degradation and problems of sustainability (cf Yergin, 2011).

Symbolic and Religious Aspects

From all over the world, myths have been collected relating how humanity first came to master fire, often in a feat of cunning and deceit (Frazer, 1930). Those myths convey a sense of the preciousness of fire, which is represented as a unique possession, separating humanity from the animal world. Many people used to tell that neighboring groups living further away in the bush did not have fire and were unable to cook their food; those stories have all been proven slanderous.

Fire is generally believed to have purifying effects. The domain of culture is seen as coinciding with the range of domesticated fire. Thus, cooked meat is regarded as edible for humans, raw meat as only fit for beasts. Similarly, land cleared by burning is trusted as belonging to the human domain, whereas uncleared bush and forest are feared as a dangerous hideout for predators, serpents, insects, and evil spirits.

The sense of preciousness has also found expression in rites. The communal fire would be the center of group life, and people would treat it as sacred, surrounding it with ceremony and taking care that it would never cease burning. The Roman cults of the hearth and of Vesta, the fire goddess, show how such ancient rites could persist in an urban setting (cf Pyne, 1997).

Yet, with urbanization, the sense of the preciousness of fire was often superseded by a general anxiety of the dangers it posed. Thus while Hindu and Zoroaster fire cults kept alive the age-old worship of fire, they were surrounded by ceremonial care. In Christianity and Islam, some old fire traditions persist, as in the burning of candles and incense. Fire no longer plays any part in beliefs about the origin of human society, however. Instead, it is strongly associated with evil. Sinners and unbelievers are threatened with a life after death in which they will be tormented by eternal burning.

Fire festivals, such as those held all over Europe on Saint John's day, when things considered impure would be committed to the flames, were occasions of combined joy and horror. Modern literature and art abound with evocations of

the terrors of fire. Most novelists who have described a blaze, attribute the disaster, quite realistically, not to natural forces such as lightning but to human action – either to personal negligence, madness, or malice, or to collective aggression, in war.

A more dispassionate way of regarding fire, not in terms of its good or bad effects upon human beings but as a natural force in its own right, was first developed by the philosophers of ancient Greece. Out of various antecedents a generally accepted doctrine emerged according to which the universe consisted of four elements: earth, water, air, and fire. In China and India similar systems of thought developed. With some variations, the view in which fire constituted one of the major elements remained the dominant cosmology for natural scientists and physicians well into the modern era.

Alchemists and chemists, as the direct successors to the metallurgists and 'fire masters' of a previous age, made the study of fire into their central concern. Just as modern mechanical industry in its initial stages owed a great deal to the steam engine, the rise of modern physical science would have been inconceivable without the laborious efforts of earlier investigators experimenting with, and theorizing about, fire.

Conclusions

The control over fire has been a human species monopoly since the Paleolithic. Access to fuel constitutes an integral part of the apparatus with which humans in general have established and continue to maintain dominance over other species, while, at the same time, it also serves as an important resource in the struggle for power and privilege among human groups.

Ever since the earliest stages of its domestication, the same sequence of events has recurred again and again in human relations with fire: deliberately sought advances in control were followed by unintended increases in dependency, and as the dependency sank deeper into the social and economic infrastructure, it tended to become increasingly less clearly perceptible. Like agrarianization, industrialization began with conspicuously huge applications of fire. As industrial production became more specialized and highly organized, so did the use of fire. In everyday life in highly industrialized contemporary societies, flames are now visibly present only in such highly domesticated guises as cigarette lighters, candles for ceremonial use, or wood fires lit to create a sphere of comfort and relaxation. When, on the other hand, a fire is shown on television or in the newspapers, it almost always spells war and disaster. The regularly controlled combustion processes upon which industrial production largely rests are mostly relegated away from public view.

In accordance with this apparent eclipse, fire has also ceased to be regarded in the natural sciences and philosophy as one of the elements out of which the world is composed. The very concept of fire has disappeared from scientific discourse, to be replaced by the more abstract concept of 'energy' – something that cannot be directly seen, heard, smelled, or felt. Similarly, many a day may pass in the life of the average citizen of a modern industrial state during which he or she does not witness any physically observable fire. In the social sciences, too, fire has become almost completely unnoticed. It can be concluded from the foregoing that this is unwarranted.

Abstract

In this article, motivations for cross-linguistic comparisons of how children acquire their native language are noted, and major approaches to the field are reviewed, from traditional diary-studies of bilingual children, via the Anglocentric orientation of early developmental psycholinguistics, to extensive data collection and research in a wide range of languages and language-types over the last two decades of the twentieth century. Claims for universal underpinnings of language acquisition are discussed, including Chomskyan-based nativist claims for formal principles of Universal Grammar (UG) on the one hand, and psychologically motivated claims for extralinguistic perceptual and cognitive constraints shared by children acquiring different languages, on the other. In production of language, children across the world proceed from prelinguistic babbling to one-word utterances and on to early word combinations, grammatical clause structure, and clause combining. Such shared trends are compared with current research which emphasizes the marked impact of caretaker input and the effect of target-language typology on very young children in a range of domains, including early speech perception and babbling; the noun vs. verb bias in children's early lexicons; spatial distinctions; null subjects; word formation strategies; expression of reference, temporality, and locative motion in narratives; and differential deployment of structural devices such as passive voice for expressing impersonal perspectives in discourse. The article concludes by noting the need for further research designed for comparability between both those languages which are typologically closely related and those which differ in critical respects.

In this article, motivations for cross-linguistic research into children's acquisition of their first language(s) are noted with a brief historical outline of the field (Section Approaches to the Field). This is followed by a review of trends which appear to be universally shared across children acquiring different languages (Section Universal Trends in Language Development), compared with the impact of typological properties of particular target languages on processes of acquisition (Section Impact of Target-language Properties). The article concludes with a note on desiderata (Section Conclusion).

Approaches to the Field

The major motivation for the cross-linguistic study of language acquisition, as of cross-linguistic research in general, is to compare what is universally shared across children irrespective of the specific target language or speech community to which they belong, on the one hand, with interlanguage variation and the impact of properties peculiar to a particular language or language type on the other (Slobin, 1997b). A related, psycholinguistically motivated question is how the specifics of target-language typology interact with acquisitional principles and strategies deriving from more general extralinguistic factors of perception, cognition, and social interaction (Slobin, 1985b).

The first studies of children's acquisition of their native language(s) which can be characterized as cross-linguistic in orientation date from the nineteenth and early twentieth centuries. These were generally diary studies of childhood bilingualism, among children raised in more than one language, mainly in Europe. Such studies provided potentially rich data for cross-linguistic comparisons, as did a range of studies of children acquiring languages other than English (Slobin, 2014). However, these were by and large not systematically directed to the testing of psycholinguistically motivated hypotheses, and they tended to focus on phonology, inflectional morphology, and the lexicon, with little concern for syntax or semantics.

The rise of developmental psycholinguistics in the USA in the 1960s created a field of inquiry which aimed to integrate insights from linguistic theory and description with developmental patternings in first language acquisition. Such studies tended to be Anglocentric, but provided a basis for research in other languages. For example, the general developmental stages delineated in Brown (1973) for the early years of grammatical development appear to apply across languages (see Section Universal Trends in Language Development below).

This Anglocentricism was countered by the Berkeley project on four typologically distinct languages (Slobin, 1982). Since then, data have been collected from a wide range of languages, both across and outside Europe. These include surveys of several dozen typologically distinct languages in the five volumes edited by Slobin (1985–1997). Other collections focus on particular domains including: early clause structure (Friedmann and Novogrodsky, 2004), the lexicon–syntax interface in verb acquisition (Lieven, 1998), and narrative construction (Berman and Slobin, 1994; Berman and Slobin, 1994). Generative grammars gave rise to a parameter-based analysis of acquisition in different languages and domains, for example, Hyams (1986) and Weissenborn (1992) on null subjects, Meisel (1992) on functional categories and the ordering of constituents (*see* Generative Grammar).

Research in child language since the 1980s has thus yielded a large body of data on acquisition of numerous languages, including ones with non-European typology. Many of the latter studies are anchored in ethnographic-type fieldwork, for example, for Inuktitut by Shanley Allen, for Mayan Quiché by

Clifton Pye, and for Sesotho by Katherine Demuth; or in research conducted by native speakers, as in Soonja Choi's work on Korean. This work combines to demonstrate that (1) children early on adapt to the particular constraints of their native-language typology, as verb-initial or verb-final, accusative or ergative, as synthetic or agglutinating; (2) they do so on the basis of the particular cultural norms for caretaker–child interaction in their speech community; (3) they do so with equal rapidity and ease across languages; and (4) within languages, the acquisition of certain subsystems may be delayed for language-specific reasons of relative structural and/or semantic complexity, on the one hand, and because they belong to restricted registers of usage not accessible to young children, on the other.

Universal Trends in Language Development

Different points of departure underlie claims about universals in language acquisition. A nativist, Chomskyan-based view will specify these in terms of the formal principles characterizing a generative model of Universal Grammar (UG) with cross-linguistic variation accounted for by differential setting of structural parameters according to the target language. A Piagetian orientation will explain them in terms of general cognitive principles and shared conceptual underpinnings which provide a universal epistemological basis for acquisition of linguistic knowledge (Slobin, 1985). The view espoused by this author is that children start out the task of acquisition equipped with categorical and semantic distinctions of the type termed by Chomsky 'substantive' as against formal universals, akin to Keenan's (1979) idea of 'naive' or primitive universals (Reilly et al., 2002). For example, children do not need to learn that there are two main kinds of sound segments, consonants and vowels; that propositions distinguish between predicates and arguments; or that there are intransitive and transitive clauses, with one-, two-, or three-place predicates.

Whatever the explanation they propose, researchers agree that there is a clear biological underpinning to the overall developmental stages manifested by children in command of language production irrespective of mother tongue. Just as children sit before they stand, and walk before they run, so children across the world babble before they produce single words, rely on single words before they start combining words, and produce isolated clauses before they join these together by increasingly specific lexical means and complex syntactic devices.

Overall progression thus involves an evolution in construction types. Language production typically starts out with utterances, as behavioral elements which provide the initial basis for expressing relations between semantic content and phonetic form. These typically take the form of isolated lexical items or unanalyzed strings of words, starting around the end of the first year of life. Structure dependence emerges when these lexical units are combined in simple-clause structure, realized by morphosyntactic markings of verb–argument relations. Next, adjacent clauses are combined, first by coordination, subsequently by various kinds of subordinate constructions – initially mainly finite and subsequently nonfinite – leading up to complex clause-linkage by derived nominalizations (Berman, 1993). This needs to be qualified for a verb-final language like Turkish, where the unmarked means of clause linkage is by nonfinite, nominalized constructions. These emerge relatively early in Turkish compared with European or Semitic languages.

With respect to acquisition of morphology, the domain in which languages tend to differ most, children generally acquire the bulk of the inflectional system of their language before they master its derivational morphology. This is understandable since inflection is more regular, productive, and grammatically obligatory than derivation. Besides, derivational processes depend on a level of vocabulary expansion not achieved by young preschool age. In fact, in some instances, like derived nominals or the high-register Latinate lexicon of English, children will master derivational processes only well into school age. In contrast, they by and large command the inflectional systems of their language by the age of three, irrespective of how morphologically opaque or synthetic these happen to be. Cross-linguistic differences affect acquisition of inflection along two main dimensions. Psychological processing principles like perceptual saliency coupled with regularity and transparency of form-meaning mappings account for the fact that, for example, Turkish-speaking children gain command of the bulk of their rich system of agglutinating, inflectional suffixes by a much earlier age than children acquiring languages with more synthetic or syncretic morphologies like Hebrew or Icelandic. And experiential factors of frequency of use in the everyday colloquial speech that constitutes the linguistic input and output of young children explain why certain grammatical categories are acquired relatively late in languages where they constitute high-register or literate constructions.

In the domain of syntax, children typically gain command of simple clause structure in their language between ages 2 to 3 years. Basic word order emerges very early indeed, first between phrasal constituents, only later within phrases. Constituent ordering is followed by grammatical marking of verb–argument relations, around the same time or somewhat before inflectional marking of grammatical agreement. The overall progression is thus much as Brown (1973) defined for English: from single words to early word combinations, thence to simple clause structure, followed by a range of devices for clause linkage.

Another commonality is the general development observed across children from rote-learning of unanalyzed items to partial productivity followed by command of structure-dependent rules and generalizations, which are subsequently constrained by conventions of lexical and discourse usage. This has been demonstrated, for example, for how children acquire the semantics, morphology, and syntax of causative verbs in three typologically distinct languages: English at the more analytic or syntactic end of the scale, Hebrew with relatively synthetic bound morphology, and Inuktitut as a polysynthetic language which marks causativity by both morphological and lexical means (Allen, in Lieven, 1998).

General language development thus proceeds across different phases, from pregrammatical to structure-dependent to appropriate use. And it becomes both more elaborated and varied in structure and use, on the one hand, and more restricted or constrained by target-language specifics, on the other. Thus, in acquiring the sound system, babies proceed

from universal crying to uttering a range of speech sounds, followed by babbling, which is increasingly restricted to elements of the native language to a point where eventually the system will be so constrained as to impose a nonnative pronunciation in other languages. Similarly, in morphology, across languages children proceed from nonalternation between forms to immature strategies for initial markings of grammatical categories, thence to 'creative errors' of overregularization, until eventually the system becomes fully constrained by lexical convention. And in the acquisition of the lexicon, again across languages, children move from a restricted vocabulary of nursery terms and over or underextensions of conventional items to a period of creative innovation; eventually the conventional lexicon takes over, while at the same time vocabulary growth is both constrained and elaborated by socially and culturally appropriate distinctions of register and usage, lasting into adolescence.

Impact of Target-Language Properties

As against these cross-language commonalities and claims for universal constraints, whether formal-linguistic or perceptual-cognitive, current research reveals a marked effect of target-language typology from a very early age. Such more language-specific claims have been explained in cross-linguistic perspective as reflecting a modified, neo-Whorfian characterization of the relation between language and thought (Slobin, 1996) and as demonstrating the critical impact of caretaker input from the very start (McDonough et al., 2003). This very early sensitivity to target-language properties has been observed in a variety of linguistic domains. For example, language-specific effects exert an influence on speech perception and babbling during the first year of life (Jusczyk, 1997). And well before they have command of grammatical inflection, children will adjust their speech output to the prosodic character of their language, as intonation or tone-based (Demuth, 1993), and they will show rapid command of vowel-harmony where required, as in Turkish (Aksu-Koç and Slobin, 1985).

Children's encoding of the semantics of space and which distinctions they mark linguistically (e.g., in shape or location of figure and ground respectively) is also markedly influenced by target-language specifics. Thus, the universality of the early preference among children acquiring European languages (and also Hebrew) for the prepositions *in*, *on*, and then *under*, which was convincingly explained in terms of perceptual properties of space and shared cognitive preferences, has now been queried, since it turns out that quite different factors govern the encoding of spatial distinctions in languages like Korean or Tzeltal compared with English and Dutch (McDonough et al., 2003). Children appear to relate to the categories relevant to their own native language without initially manifesting universal patternings in the expression of spatial distinctions.

Null subjects are another domain in which Universalist claims have been made. Thus, Hyams (1986) suggested that children first set the prodrop parameter to the unmarked value of plus, irrespective of target language, since English-speaking children in the early stage of grammar acquisition produce numerous subjectless sentences, as do their Italian peers. Weissenborn (1992) showed, however, that target language input has a marked influence from very early on in this respect, since children acquiring French produce fewer subjectless sentences than those acquiring German, and the latter do so less than children acquiring strongly prodrop languages like Italian and Spanish.

The very early impact of target language is evident not only in which categories are distinguished, but also how. This is clearly shown in Clark's (1993) cross-linguistic comparisons in the domain of word formation. When young children express the notion of 'undoing' or reversal of actions, they do so from early on in ways peculiar to their native tongue: by the prefixes *un*-in English and French *dé*-, and by particles like *ab* and *aus* in German, *af* and *uit* in Dutch. Hebrew-speaking children, in contrast, must do this lexically or periphrastically, since their language lacks the morphological means for this semantic category. Similarly, in order to express causativity, children will start by using syntactic means with verbs like *make* in English and *faire* in French, a construction type used only rarely by Hebrew-speaking children for this purpose. Subsequently, English-speaking children will overextend verbs like *fall* or *sing* to transitive contexts; in Inuktitut, children will first use morphological and then lexical means of causativity while in Hebrew, they will first neutralize and then alternate morphological patterns to mark verb transitivity (Allen in Lieven, 1998; Reilly et al., 2002).

This research converges to suggest that apparently universal acquisitional principles of structural simplicity and semantic transparency in form-meaning mappings are affected and perhaps even superseded by typologically pervasive properties of the target language. For example, it has been argued that children will find it easier to juxtapose words than to affix bound elements to a stem or root, and that these processes are perceptually more salient and so more accessible to young children than stem-internal vowel alternation. However, in a language like Hebrew, which uses vowel alternation to express basic grammatical distinctions such as verb-tense, children mark past vs. present tense at much the same time as their counterparts acquiring languages which use more linear morphological means. Moreover, although their language allows both noun compounding and external, linear affixation to a stem for new word formation, Hebrew-speaking children typically innovate nouns, verbs, and adjectives by the more typically Semitic device of attaching syllabic affixes to a consonantal root: and they rarely use the option favored by English-speaking children for creating novel verbs by zero derivation or syntactic conversion (Berman, 1999).

Children's acquisition of word classes and the composition of their early lexicon are other areas which suggest that claims for universal underpinnings of acquisition may need to be modified. Prior research on children's lexical repertoire at the one-word stage in several languages showed that more nouns were acquired earlier than verbs, while the vocabulary spurt in the period before early word combinations also consisted mainly of noun like terms. Gentner (1982) explained this in terms of general cognitive principles, since verbs as relational terms are holistic rather than coherently packaged entities, while nouns (at least those in the input and output of one-to two-year-olds) tend to encode semantically 'natural' categories that refer to concrete objects which are perceptually identifiable. Recent research has shown, however, that this noun bias

may be an artifact of the nature of the lexicon and lexical input in the target languages, and that in some cases, verbs may be acquired earlier and in greater quantities than nouns (for example, the studies by Tomasello 2003 and by Choi in Lieven, 1998).

At more advanced stages, developments in form-meaning mappings in extended discourse provide further evidence for the impact of 'typological imperatives.' A five-language cross-linguistic sample of picturebook narratives produced by children aged three to five and nine-year-olds compared with adults (Berman and Slobin, 1994) showed that the expression of textual temporality was critically affected by native-language tense/aspect systems even among our youngest subjects. In Hebrew, children marked only grammatical tense, in Spanish they distinguished both simple from progressive and perfective from imperfective aspect, while in Turkish they gave grammatical expression to modality. Moreover, there was no evidence for 'compensation' in the sense that children attempted to give lexical expression to notions not grammatically encoded in their language (e.g., by using periphrastic adverbs to mark aspectual distinctions in languages like German or Hebrew). On the contrary, not only 'do speakers tend to limit their attention to those semantic distinctions marked in the grammar, they may even overattend to such distinctions in early phases of development' (Berman and Slobin, 1994, p. 619). Slobin (1996, 1985–97) has since extended these observations to the expression of locative trajectories. Proceeding from Talmy's (1985) distinction between verb-framed languages (Hebrew, Spanish, and Turkish in our sample) and satellite-framed languages like English and German that rely heavily on locative particles, he shows that the way young children – like adult speakers of the same language – talk about motion, paths, and directionality depends critically on how these notions are grammatically and lexically encoded in their language. Here, too, the underpinnings of such distinctions are evident very early: at the one-word stage, Germanic-speaking children use particles like *off* or *aus* to express direction of motion in ways encoded by verb-stems by children acquiring French, Spanish, or Hebrew. For example, at the age of 18 months, my Hebrew-English bilingual daughter would say either English *down* or a truncated stem form of the Hebrew verb *la-redet* 'to get/go down,' when she wanted to be taken out of her high chair.

In another cross-linguistic project comparing children's narrative texts produced by children aged from 5 to 15 years on the basis of two picture-series, Hickmann et al. (1996, p. 391) focused on the devices for introducing, maintaining, and shifting reference to characters in a story. They found that the English, French, German, and Chinese 'rely differentially on local vs. global devices to mark newness: postverbal position is obligatory in Chinese …, indefinite determines in the other languages; across languages: newness markings emerge late (age 7), local markings emerge before global, and local and global markings are strongly related.' Their findings point to an important interaction between shared developmental trends and linguistic specificity. Relatedly, in the Berman and Slobin (1994) study, across languages, three-year-olds tended to relate to each picture in isolation, four- and five-year-olds were able to encode linearly expressed local relations between events in terms of local temporal relations of sequentiality and subsequently of causality, school-age children constructed a globally organized hierarchical narrative, and adults tended to adopt individual rhetorical styles with rich interpretation and a personal narrative stance.

Ongoing cross-linguistic research on the production of narrative and expository texts by schoolchildren and adults reaffirms such interaction between generally shared developmental trends and typologically determined expression of semantic distinctions and selection of rhetorical options. Nine-year-olds can all construct well-formed personal experience narratives, but are unable to produce coherent expository texts. Further, only from high-school age will one find consistent, deliberate, and appropriate differentiation between language usage across spoken and written texts, marking highly language-particular register distinctions. In contrast, overall genre distinctions appear similar across languages. For example, narrative texts are couched in past tense and mainly perfective aspect, and they have light subjects (mainly pronominal in English and French or null subjects in Hebrew and Spanish), while expository texts rely more on generic or extended present tense and have more lexical and heavier, more noun-phrase subjects and objects. This, too, interacts with target-language options and preferences. For example, in order to express a detached, impersonal perspective in English, passive is quite widely used even by grade-school children, increasingly by adults; and passive is also quite common in the Icelandic texts. In contrast, passive is used far less in other languages, even though it occurs as a structural option: Swedish subjects rely heavily on the impersonal pronominal *man* corresponding to the very common use of *on* in French; Spanish and Hebrew achieve the same rhetorical effect by means of subjectless or second person impersonal constructions. Similar patterns emerged for differential use of pronominal compared with null subjects and also for relative clauses as devices for syntactic packaging in the picturebook narratives.

Discourse-based cross-linguistic comparisons thus suggest that reliance on certain linguistic forms may depend not only on structural factors of relative morpho-syntactic complexity or productivity, but also on the extent to which a given rhetorical option is favored for specific discourse purposes in current language usage.

Conclusion

In sum, on the basis of shared cognitive and linguistic universals, even very young children are attentive to key typological properties of their language. From an early age, they recognize 'where the action is at' in the input language, not only which categories are formally distinguished, but also how. *When* this type of sensitivity finds expression will depend on general developmental, largely extralinguistic factors. For example, the spatial distinctions studied by Bowerman (1995) and her colleagues will precede command of derivational marking of linguistic subcategories, and these will emerge earlier than rhetorical mastery of linguistic forms in the context of extended narratives. But in each case, the specific ways in

which children encode form-meaning relations accord with how this is done by adult speakers of the same target language rather than by children of the same age in other languages.

As noted in the introduction, a large body of data is currently available for acquisition of different domains in a rich range of languages from Europe and elsewhere. What now seems necessary is to extend systematic and deliberately comparable research designs across a range of languages and linguistic domains – along lines conducted for morpho–syntax by Slobin (1982), for word formation and derivational morphology by the structured elicitation and diary studies reported in Clark (1993), for semantic encoding of space by Bowerman (1995), for temporality by Weist and coworkers (Weist et al., 1993), as well as for narratives by Hickmann et al. (1996) and by Berman and Slobin (1994). Such studies might profitably focus on two contrasting directions of cross-linguistic comparison: (1) languages which are typologically very distinct, for example, ergative or accusative, verb-initial or verb-final, analytic vs. synthetic or agglutinating; and (2) languages which are typologically close, like Dutch and German, or Arabic and Hebrew, but which differ along certain restricted dimensions. Such work should aid in specifying the relative weight of the various factors touched on here. It would help to delineate the interaction between language-universal and language-particular, between intralinguistic, cross-linguistic, and extralinguistic factors in acquisition. And it could provide psycholinguistic motivation for the distinction between language-specific, typologically shared, and cross-linguistic or universal features of language structure and use in developmental perspective.

Abstract

Chomsky's theory of Universal Grammar (UG) is introduced to explain children's rapid convergence on the grammar of their local language. A system of innate principles and parameters guides children's acquisition of language. Children are shown to misset certain parameters causing them to hypothesize properties not observed in the language of the community. Children's temporary missteps are put aright with input from the surrounding language. The misset parameters are predicted by the theory of UG but not anticipated by usage-based theories of language acquisition.

Introduction

Every parent is fascinated by their child's rapid and seemingly effortless acquisition of their first language. The rapid strides children take in acquiring language seem particularly impressive when considered alongside other cognitive skills such as getting dressed, hopping, counting, and so on – skills that appear to take much more conscious practice. This article examines how children's acquisition of language is accounted for by Chomsky's theory of Universal Grammar (UG). Chomsky's theory of UG is a linguistic theory that posits an innate language faculty and, for this reason, is often referred to as a 'nativist' account (e.g., Chomsky, 1986, 1995). On this account, UG has a role to play in guiding children's rapid path to acquisition of their local language. Using UG as a guide, children have to identify various syntactic and semantic properties of their target language in the linguistic input and incorporate these into their grammar. At the same time, children must learn the lexicon of their language from their caretakers, and map this onto the structures made available by UG.

With UG in place, any typically developing child across the globe is ready to tackle acquiring the language of their community. As we will demonstrate, however, there are times when UG appears to initially steer children to flaunt the linguistic input that surrounds them. It is worth exploring these data, since a path that deviates from the surrounding linguistic input is not anticipated by alternative 'usage-based' accounts of language acquisition. Usage-based accounts of language acquisition expect children to attempt to follow the model provided by adults (Ambridge and Lieven, 2011; Goldberg, 2003, 2006; Tomasello, 2000, 2003). Usage-based linguists place a much heavier burden on the linguistic input, since the child has no advance linguistic knowledge. Not only do children learn the lexicon from the input, they must rely on the input to learn syntactic categories (such as 'noun phrase' or 'verb phrase'), to learn sentence structure, and to learn which structures and meanings for sentences are permissible and which are excluded from the language. On this view, children draw on the general learning mechanisms used to gain other kinds of cognitive knowledge and apply them to the task of acquiring language. We will demonstrate that the UG approach to language acquisition can explain data that is a challenge for usage-based approaches.

Chomsky's Theory of UG

Chomsky has argued that linguistic knowledge is part of our genetic endowment as human beings. The proposal is that children are born with a 'UG,' a domain-specific computational mechanism that is part of the language faculty. This mechanism supports language acquisition to ensure that it takes place in a rapid, effortless, and relatively error-free manner, despite considerable latitude in children's experience. In the following sections, we illustrate the predictions of the theory of UG for cross-linguistic acquisition. We first address the system of parameters that comprise part of the language acquisition device. Parameters are designed to address the rich diversity observed in the languages of the world.

Parameters

According to Baker (2001), "A parameter is simply a choice point in the general recipe for a human language." Continuing with the analogy to baking, Baker (2001) states: "A parameter is an ingredient that can be added in order to make one kind of language or left out in order to make another kind. A parameter could also be a combining procedure that can be done in two or three ways to give two or three different kinds of languages. If you take the generic ingredients of language, add spice B, and shake, you get English. If you take the same basic ingredients of language, but instead of spice B you add flavorings D and E and stir, you get Navajo" (Baker, 2001, p. 57). The human language recipe makes clear that languages that have most of the same basic elements, but one different property could make the language look very different on the surface.

There are a number of models of parameters currently under debate (cf Thornton and Crain, 2013). One point of debate is the scale of the proposed parameters. Some researchers propose that there are 'macroparameters,' large-scale typological parameters that have wide-reaching effects, while recent research tends to favor 'microparameters,' which account for small-scale variation. Baker (2001) envisages a large-scale hierarchy of parameters. The first parameter encountered by the learner at the top of the hierarchy designates the language as polysynthetic or not. Polysynthetic languages are ones which have very complex long words that, if translated into English, might be expressed as a full sentence. If the learner

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53008-6

chooses the setting for a polysynthetic language, decisions relevant only for polysynthetic languages follow. If the learner chose the nonpolysynthetic parameter setting, a host of different decisions follow. Current models of parameters also can be distinguished by whether learners encounter parameters in a specific order, or whether order is unimportant. Another point of debate is the amount of input required to set a parameter. Does abundant input result in swifter setting of the parameter? Do children need a fixed amount of input before a parameter is set, or is just witnessing a particular type of data in the positive input sufficient? Does the learner initially begin with one particular setting of the parameter, and are they free to choose between two options, or do they engage both settings of the parameter until the input data resolve which one correctly matches the linguistic input? All of these issues make for lively debate. Despite the debate, there is, nevertheless, agreement in the generative linguistics field that parameters sit at the heart of cross-linguistic variation.

From the perspective of first language acquisition, parameters accelerate the learner's path to the adult grammar of the language of the environment, whatever it happens to be. All the learner need to do is fill out the menu of choices in consultation with the local language. The benefit is that the learner is kept 'on track' to converge on the adult grammar without mistaken hypotheses that would slow acquisition. The next section illustrates how parameters work with some examples from the empirical literature.

Parameters and Cross-Linguistic Acquisition

Parameters assist in guiding children's acquisition of syntactic and semantic properties. Those parameters that guide very basic properties of language such as word order are likely to be set early in the course of acquisition (Wexler, 1998). Indeed, there is little evidence from children's productions that they make word order errors. Other properties of languages can take more time to settle on. We will see one example from semantics where children are slower to map their initial hypothesis for a parameter onto the local language.

Let us begin with examination of the parameter known as the *wh*-parameter, originally proposed by Huang (1982). This parameter captures a two-pronged cross-linguistic difference in the position in which question words (*wh*-words, e.g., who, where, what) are pronounced. In languages like Chinese and Japanese, question words are produced 'in situ,' in the position of the phrase that is being questioned. This can be illustrated in (1), where it can be seen that in Mandarin Chinese, the question word for what 'shenme' is positioned after 'eat' as in 'The alpaca is eating what?'

1. Yangtuo zai chi **shenme?** Mandarin Chinese
   Alpaca be eat what
   'What is the alpaca eating?'

(2) the alpaca is eating what English Movement
what is the alpaca __ eating ____

In English and other Romance and Germanic languages, the question word originates in the base position in which it is pronounced in Chinese or Japanese. It is then assumed to move to the highest position in the hierarchical sentence representation, where it is pronounced. In English, the auxiliary verb (*is* in (2)) also moves to achieve the correct word order. Children use the language input to decide if their language is the Chinese type or the English type, and set the parameter accordingly. Assuming that the data that children need to set the parameter is abundant, children can be predicted to set the parameter early. In this case, word order is also implicated, which is perhaps another reason to expect early mastery of the position of the question word. At any rate, cross-linguistic reports suggest children do not misplace the question word. Of course, one might be tempted to say there is no parameter – children simply copy what they hear in the language input. This would be a reasonable hypothesis for the position of question words, but it will not work for some other cases we will consider.

Let us turn to another kind of question, in which the question word originates in an embedded clause; these are known as 'long-distance questions.' In English long-distance questions, the question word is pronounced, as before, in initial position, as shown in (3). Syntactic theory proposes that the question word must move in a local fashion, passing through the position between clauses on its way to the highest position in the main clause. In (3), it can be seen that the question word originates in the embedded clause after 'eating.' It then moves between clauses, which is shown by 'what' in small print, and finally to sentence initial position.

(3) you think the alpaca is eating what English Movement
what do you think what the alpaca is eating ___

'What do you think the alpaca is eating?'

It is interesting that some languages and language dialects including German and Dutch dialects, Frisian, Afrikaans, Romani, and Passamaquoddy, record the passage of movement of the question word in a position between clauses as well as sentence-initially. In some German dialects, for example 'who' (*wen*, which is the accusative form of the question word) can be copied, as in (4):

4. Wen glaubst du, wen das Alpaka küsst?
   Who think you who the alpaca kisses
   'Who do you think the alpaca is kissing?'

Turning to children's productions of long-distance questions, children acquiring English (Thornton, 1990; Crain and Thornton, 1998) and also Dutch (Van Kampen, 1997), French (Jakubowicz and Strik, 2008), Basque, and Spanish (Gutierrez, 2004, 2006) have been found to pronounce the question word between clauses, even though the adult grammar of these languages does not permit the copy of the question word between clauses. Thornton's (1990) finding for English using elicited production techniques was that just some children produce these '*wh*-copying' structures. *Wh*-copying questions in children's productions are shown for a range of languages in (5). (It is important to distinguish questions with a copy of the question word (*wh*-copying structures) from questions in which a scope marker is in the highest position and the true question word is positioned between clauses. In English, this would amount to a question like 'What do you think who is under there?' to mean 'Who do you think is under there?' This is known as 'partial movement.' It is a very productive structure in many languages, and also appears as a nonadult structure in child language in a number of languages, but it is not the structure under discussion here.)

5. a. English, Thornton 1990
   Who do you think *who*'s under there?
   Who do you think *who* jumped over the can?
   b. Dutch, Van Kampen, 1997
   Wat denk je *wat* ik zie
   what think you what I see
   'What do you think I see?'
   c. Basque, Gutiérrez, 2004
   Nor uste duzu nor bizi dela etxe horretan?
   who think aux-2SG who lives aux-comp house that-in
   'Who do you think lives in that house?'
   d. Spanish, Gutiérrez Mangado, 2006
   Dónde crees dónde ha ido el niño?
   where think-2sg where has gone the child
   'Where do you think the child has gone?'
   e. French, Jakubowicz and Strik, 2008, p. 120
   Où Lala a dit où le poisson nage?
   where Lala has said where the fish is swimming?
   'Where did Lala say that the fish is swimming?'

The possibility of pronouncing the copy of the question word between clauses varies cross-linguistically, so this can be termed a parameter. As Rizzi (2009) proposes, some parameters focus on such differences in pronunciation, while others target structural properties.

The empirical facts from languages studied to date show that children from a variety of languages produce the *wh*-copying structure, despite the fact that it is not part of their language input. These facts would be puzzling on a usage-based theory of language acquisition. There is no reason to expect children from diverse language groups to produce questions with a *wh*-copy between clauses in the absence of any evidence in the language input. The facts are unsurprising on the theory of UG, however, since the parameter simply presents the option of pronouncing the intermediate copy of the question word or not. There still remains the question of why children do not immediately set the parameter in accordance with the input produced by adults in their environment, however. Most likely, children have little experience with long-distance questions. In most circumstances, a simple question is sufficient to fulfill communicative requirements. Once placed in a context that specifically calls for a long-distance question (such as asking a puppet what he thinks or believes in an experimental context), it could be that children simply guess which parameter setting is correct for their language. This explanation would explain why some children produce long-distance questions with a copy and others produce adultlike question from the start. For those children who guess the non-English parameter setting, positive evidence from the language will provide evidence for the alternative 'menu' choice.

Language acquisition researchers working within a usage-based framework have responded to the empirical findings from English. The proposal is that children attempt to be creative by merging familiar question structures (Dabrowska et al., 2009). Children are claimed to overlay the templates *What do you think?* and *What the alpaca is eating?* The first question is a direct question and the second one, *What the alpaca is eating?* is 'cut' from an indirect question such *as I know what the alpaca is eating* and 'pasted' together with *What do you think?* to form the child's copying structure *What do you think what the alpaca is eating?* The problem with the 'cut and paste' strategy is that without advance knowledge of which combinations of questions yield grammatical complex questions, children potentially could create many ungrammatical combinations. For example, indirect questions can be nonfinite as in *I know what to eat*, so the child could paste *what to eat* together with *What do you think?* to form *What do you think what to eat?* Such questions are not attested in languages that allow *wh*-copying and neither have children been found to use a *wh*-copy in questions with infinitival clauses (see Thornton, 1990; Crain and Thornton, 1998). The same is true for complex question phrases such as 'which boy.' Questions with a copy of a complex *wh*-phrase are not attested in languages that allow a wh-copy, and neither are they found in children's copying productions. It is not clear how these would be excluded by Dabrowska et al.'s proposal that children overlay templates. These ungrammatical question forms would be difficult to recover from without 'negative evidence.' For further discussion of these data and further facts that align with this parameter, see Crain and Thornton (2011).

Children may also initially hypothesize a parameter setting that is not reflected in the local language for learnability reasons. This can be illustrated with a parameter that encodes scope relations between logical expressions. This parameter was proposed originally in work by Goro (2004) and explored in subsequent research by Crain and colleagues (see e.g., Crain et al., 2006; Crain, 2012).

Scope ambiguities typically arise when two logical operators appear in the same clause. One example is sentences with negation and disjunction. In negated disjunctions in English, negation takes scope over disjunction, so disjunction yields a conjunctive entailment. For example, (6) entails that Ted didn't order pasta and Ted didn't order sushi. This shows that English negative statements with disjunction correspond to one of de Morgan's Laws of propositional logic: $(A \vee B) \Rightarrow A \wedge B$.

6. Ted didn't order pasta or sushi.

Other languages, including Japanese and Mandarin Chinese, assign the opposite scope relations. In (7), the Mandarin disjunction word for 'or,' *huozhe*, appears with negation, *meiyou*. Although the surface order of negation and disjunction are the same in Mandarin as in English, adult speakers of Mandarin judge (7) to mean that Ted didn't order sushi *or* Ted didn't order pasta. Adult speakers of Mandarin accept (7) in three circumstances, where (i) Ted ordered pasta, but not sushi, (ii) Ted ordered sushi, but not pasta, and (iii) Ted ordered neither pasta nor sushi. In logic, the corresponding formula for the interpretation of (7) in Mandarin is $(A \vee B)$, which does not entail $(A \wedge B)$.

7. (*Wo cai*) *Ted meiyou dian yidalimianshi huozhe shousi*.
   (I guess) Ted not order pasta or sushi
   'It's either pasta or sushi that Ted did not order'

The different interpretations across languages are attributed to a parameter, called the disjunction parameter. In one class of languages, disjunction takes scope over negation in simple negative sentences. Let us call this the (OR > NEG) value of the parameter. In the second class of languages, negation takes scope over disjunction, so this is the (NEG > OR) value. Another difference across languages is the interpretation that is assigned to negated conjunctions, as in *Ted didn't order both sushi and pasta*, but we will restrict our attention to disjunction here.

It has been proposed that children's initial settings of scope parameters are constrained by a learning principle called the semantic subset principle (Crain et al., 1994) that is part of UG. If we apply this to the disjunction parameter, it is easily verified that the circumstances in which sentences are true on the (OR > NEG) value comprise a superset of those circumstances that make sentences true on the (NEG > OR) value. In other words, the binary values of the parameter are in a subset/superset relation. To see this, note that the NEG > OR value yields a 'neither' reading, whereas the OR > NEG value yields a 'not both' reading. Clearly, the statement *neither A nor B* is true in a subset of the circumstances corresponding to the statement *not both A and B*. When parameter values are in a subset/superset relation, a principle of learning dictates that children acquiring all languages must initially select the subset value. In this case, they can use positive evidence to add the extra interpretations. If they chose the superset value, there would not be positive evidence available for them to reset the parameter to the correct value.

Adopting the semantic subset principle, Goro (2004) predicted that children learning languages like Mandarin and Japanese (which Goro studied) would initially interpret (6) in the same way as English-speaking children and adults interpret *Ted did not order pasta or sushi*. That is, children acquiring Mandarin were predicted to initially set the parameter to (NEG > OR), which would be different from adults. If so, then children should generate a conjunctive entailment for (6), whereas adult speakers do not. In short, the commonality that is predicted is between Mandarin child language and English rather than between Mandarin child language and Mandarin adult language.

The prediction, then, is that children learning Mandarin and Japanese would initially speak a fragment of a foreign language, in this case a class of languages that includes English. This prediction was first confirmed in an experimental study of Japanese-speaking children, reported by Goro and Akiba (2004), and has been replicated in Mandarin-speaking children by Jing et al. (2005). Children acquiring both languages generate a conjunctive entailment for disjunction when it appears in the scope of negation, whereas adult speakers of both languages do not. See Crain (2012) for further contexts where similar cross-linguistic differences emerge.

The interpretations assigned by children are evidence that children acquiring both English, Japanese and Mandarin favor the subset value of the relevant parameters. Children hear the further interpretations that are possible in the language of adults, and use these data to reset the parameter to the correct value. This guarantees that children will converge on a grammar that is equivalent to those of adults in the same linguistic community. So, this view explains why some children deviate from the adult language of their community, while at the same time, children learning other languages conform. On usage-based accounts of language acquisition, however, the initial mismatch with adults that we have observed is not anticipated, and would be difficult to explain, since children are not acting in concert with the linguistic data in their environment. Another puzzle for usage-based accounts would be why the nonadult interpretations that children hypothesize are observed in children acquiring a range of typologically unrelated languages. In the next section, we consider how universal principles of UG put their mark on cross-linguistic language acquisition.

Universal Principles and Acquisition

Children harness UG as they engage with linguistic input from parents and caretakers. The principles that are part of UG constrain children's hypothesis space, eliminating hypotheses that would permit sentence forms and sentence interpretations that are not part of the adult grammar. The theory posits universal principles, in part, as a solution to empirical findings from Brown and Hanlon (1970) among others, that parents and caretakers tend not to correct children's productions for ungrammaticality. Instead, parents respond to the truthfulness of their children's utterances. For this reason, parents are said not to provide 'negative evidence' – that is, correction for ill-formed strings of words or for meanings that are not permissible. Without parental guidance about what sentences are not grammatical or what is not a legitimate meaning for a sentence, children would have difficulty learning the bounds of the adult grammar from positive evidence alone.

One universal principle that has been widely discussed in the literature is 'structure dependence.' This principle limits children to operations or rules that are based on hierarchical

representations for sentences. In effect, children should not hypothesize rules that are based on the linear order of words. This is true, no matter what language is being acquired. One characteristic of cross-linguistic acquisition, then, will be the absence of rules in children's language that could be said to violate structure dependence. More broadly, children's productions will never feature properties ruled out by principles, and children will never give sentence interpretations that are prohibited by universal principles. As far as cross-linguistic acquisition is concerned, then, universal principles are identifiable by the absence of the phenomena they prohibit. Here we will examine a particular example from English that has been debated at length in the literature. This concerns children's hypotheses about the relationship between ordinary sentences and their question counterparts.

In generative linguistic theory, ordinary declarative sentences are related to their yes/no question counterparts via a movement rule. Children need to observe declaratives and yes/no questions in the linguistic input and formulate a movement rule that works more generally. Imagine the child is faced with the following mini-set of data in (8). All of these sentences and questions are 'simple' sentences, and we can assume these make up the majority of the input data.

8. a. Alpacas are cute — Are alpacas cute?
   b. The alpaca is eating — Is the alpaca eating?
   c. The cute alpaca can run fast — Can the cute alpaca run fast?

Children could, in principle, come up with various hypotheses about how yes/no questions are derived. If children were able to entertain linear hypotheses, based on the order of words in the sentences, they could potentially come up with the rule in (9). This rule refers to notions like 'first,' so this would entail counting from left to right to identify the auxiliary verb that is to be moved.

9. Move the first auxiliary verb/modal to sentence initial position

This linear hypothesis would, nevertheless, correctly predict all the grammatical yes/no questions in the right hand column in (8). It would incorrectly predict the form of a more complex question, as in (10), in which the noun phrase that is the subject of the sentence is modified by a relative clause. That is, 'alpaca' is modified by 'that is eating.' In (10), the first auxiliary verb that you come to when encountering the string of words from left to right is 'is,' inside the relative clause.

10. The alpaca that is eating can run fast — *Is the alpaca that eating can run fast?
    ✓Can the alpaca that is eating run fast?

The universal principle of structure dependence should not permit children to hypothesize a rule like (9). Instead, their knowledge that movement rules are formulated in terms of elements in a hierarchical structure would guide them to use notions like 'auxiliary verb in the main clause,' as in (11) which would correctly target 'can' for movement:

11. Move the auxiliary verb in the main clause to sentence initial position

The example from yes/no question formation applies to English but structure dependence has broad application to all languages. No child learning any language should test linear hypotheses.

Usage-based theories of linguistics deny that our hypotheses are guided by linguistic principles specific to the language faculty. Ambridge et al. (in press) for example, claim that more general cognitive conceptual structure maps onto relevant linguistic units. The idea is that a noun phrase modified by a relative clause as in *The alpaca that is eating* is the same kind of functional unit as *the alpaca*, or *the cute alpaca* and therefore these functional units will map onto linguistic units in children's questions. One might question whether this is a tendency or an absolute prohibition like a universal principle. Either way, the empirical findings from child language reported in Crain and Nakayama (1987) are that children are not found to consider hypotheses that would cause them to ask structure dependence violating questions like *Is the alpaca that eating can run fast?*

This concludes our short tour of the theory of UG and its explanation of children's acquisition of language. We have seen that biological endowment of principles and parameters, for the most part, speeds children's path to convergence on the adult grammar. Occasionally, children misset parameters. This may be because their initial guess is incorrect, or because they are guided by a learnability principle. The result is that children temporarily hypothesize properties that are not matched in the grammars of adults around them. Such cases are important for two reasons. They cause us to question the common sense notion that children learn everything about language from their parents. Second, they present empirical data that can adjudicate between current theories of language acquisition.

Abstract

The First World War was the first 'total war' in history, in the sense that it pitted industrialized imperial powers in a conflict that lasted for 50 months, drawing in the resources of the whole world and killing more soldiers in combat than any previous war to date. Its causes were built into the imperial and economic antagonisms of world powers for control of Northwestern Europe, and thereby for control of the empires they commanded. Its consequences included the construction of state capitalism, a mixed form of private ownership and public management, the emergence of a communist revolution in Russia, threatening to build a 'red bridge' across Europe, and a disgruntled and militarized minority in Germany and Italy prepared to overthrow the postwar order when the time was right. The Great War solved none of the conflicts that had brought it about; its demographic and economic effects were devastating, and it merely rearranged the explosive materials of international politics so that they could be set alight again in 1939.

The First World War was the first 'total war' in history. Its dimensions were greater, its casualty lists longer, its propensity to draw into its orbit all social and economic forces more powerful than any previous war in history. The conflict was not so much 'total' as 'totalizing,' tending to the full mobilization of all the resources of the combatant powers. Seventy million men put on uniforms; 9 million died on active service. What turned these differences in the scale of warfare into differences of kind was the fact that the conflict was fought between fully industrialized powers. Thus the stalemate; thus the lethality of warfare; thus the terminal effect of defeat on the imperial structures of Germany, Russia, Austria–Hungary, and Turkey. The Allies won because of their greater resources as imperial powers and because of their greater sophistication in distributing goods and services between military and civilian claimants. Democracies waged 'total war' more efficiently than dictatorships.

Causes

The outbreak of the First World War in the summer of 1914 has been attributed to accident, design, and confusion. The first position suggests that no one intended that armed conflict would break out in 1914; the second, that German and Austrian military elites planned the conversion of a Balkan diplomatic crisis into an armed confrontation; the third, that political and military leaders throughout Europe began to maneuver with some notion that war was possible, but found that they could not resist the momentum of confrontation (Joll, 1992).

What was the sequence of events subject to these interpretations, and which has commanded the support of most historians who have addressed the issue of the descent into war in 1914? On 28 June 1914, the Archduke Franz Ferdinand of Austria–Hungary, heir to the throne, was assassinated in Sarajevo. The crime was carried out by a group of Serb student patriots from neighboring Bosnia, then a province of the Austro–Hungarian empire. Their aim was to demonstrate the force of Slavic nationalism, and to challenge the domination of these south Slavic lands by imperialists in Vienna and Budapest.

In this aim, they succeeded completely. The government in Vienna decided to make this crime a matter of state, and to lay the blame for this political murder on the independent Kingdom of Serbia, and its intelligence services. On 5–6 July, Austrian officials went to Germany to seek support for their policy of making Serbia 'pay' for the assassination. German officials gave their approval, offering a 'blank check' to their Austrian allies. With this backing, on 23 July, the Austrians presented Serbia with a list of demands that constituted a challenge to the status quo in the Balkans.

This is where Russia entered the conflict. A humiliation for Serbia would humiliate her Slavic ally, Russia. With Russian backing, Serbia met most of the Austrian demands, but refused to capitulate completely. In support of Serbia, Russia ordered partial mobilization of her armies on 29 July. In support of Austria, and in response to the numerical superiority of Russian forces, the German army mobilized too.

Once German mobilization was in progress, the crucial link appears between a conflict in the Balkans and an all-European war. German military planning had for years established a set of priorities to safeguard the security of the German empire. The primary point here was the need to avoid fighting a two-front war. Thus, it was necessary for Germany to eliminate a Western threat on the part of Russia's ally, France, before facing the huge armies Russia could put in the field. To do so, a military plan – the Schlieffen plan – was developed through which German forces could move in a huge arc from Cologne in southwestern Germany westward through Belgium and then southward through France. The destination, after 42 days, was in the vicinity of Paris, where the French army would be destroyed, just as had occurred in 1870.

The Schlieffen plan was thus a German response to the threat of a two-front war. That threat had materialized out of the confrontation of Germany's ally Austria–Hungary with Russia's ally Serbia. But the German plan to destroy the French army by an arcing move through Belgium threatened to bring in the United Kingdom, guarantor of Belgian independence (Ritter, 1958).

And that is precisely what happened. The German invasion of Belgium precipitated a state of war among the five great powers: Germany and Austria–Hungary on one side, and France, Russia, and the United Kingdom on the other. By 4 August 1914, the First World War had begun.

Had anyone intended this moment to occur? Probably not. While the chief catalyst of the war crisis was the decision by Austria and Germany to press Serbia to pay a political price for the assassination, the outbreak of war was less a conspiracy than a complex mixture of arrogance, a sense of national 'honor,' ignorance, and confusion. All the actors in this drama misjudged each other. Each move forward in the crisis was followed by a further heightening of tension. First Austrian honor was at stake, then Russian honor; then German fears of encirclement led her to respond to a perceived threat from Russia by threatening Russia's ally, France, and when confronted by a likely invasion of France, the United Kingdom hesitated, and then in defense of her honor, she declared war on Germany.

Two elements in the crisis were crucial in preventing a diplomatic solution. The first was temporal; the second, structural. First, timing. The war crisis lasted for 1 month. But a closer view of these events presents us with an even shorter timetable in the slide toward war. One week separated the Austrian ultimatum to Serbia – on 23 July – from Russian and German mobilization – 29–31 July. In that time period, it was simply impossible for alternatives to be explored, or for the weight of antiwar and pacifist opinion, by no means negligible, to be brought to bear on political leaders. The crisis moved too fast to be stopped.

The second determinant of a general European war was, broadly speaking, structural. That is, the chronic instability of southeastern Europe was insufficient in and of itself to bring the Great Powers to war. What turned a minor conflict into a major crisis was the linkage between the Balkan conflict and the longer term balance of power between Germany and the United Kingdom. Once the United Kingdom and Germany were aligned on opposite sides, then the crisis of 1914 became a contest for control over northwestern Europe. Should Germany defeat France in 1914, as she had done in 1870, the German navy would occupy the Channel ports. British shipping lanes, necessary to feed her home population, would be open at the pleasure of the German navy. No British government could accept that prospect (Kennedy, 1980).

It is true that the British Foreign Secretary, Lord Grey, did not make this issue clear in his diplomatic handling of the war crisis. The German Chancellor Bethmann-Hollweg hoped that the United Kingdom would stay out of the war. But geographical and strategic imperatives overshadowed diplomatic miscalculations. An invasion of Belgium and France posed a real and present danger to British vital interests. And when the United Kingdom entered the war, so did the British empire. What had started in Sarajevo, echoed in Sydney, Capetown, and Calcutta. By 4 August 1914, the world was indeed at war.

Conduct

The 1914–18 war spanned the globe, but its outcome was determined by what happened on the battlefields of Western Europe. This article therefore offers an outline of the major military encounters of the war, encounters that left lasting traces both on the landscape of Europe and on the contours of the rest of the twentieth century.

The battlefield in 1914 was Victorian in character. Artillery provided more fire power than ever before, but most of it was horse-drawn. Four years later, the battlefield was transformed. By the end of the war, it took on contours recognizable to most soldiers who would come to fight in later conflicts. Infantry, artillery, tanks, and air power were all coordinated through communications systems and supply systems of great complexity and sophistication. Supplying animal power meant relatively little; supplying machines meant everything (van Creveld, 1977). The 'storm of steel' in the words of the German infantryman Ernst Jünger had come to stay (Jünger, 1929).

1914

The two major military encounters of 1914 produced very different outcomes. In Belgium and France, the German army, 1 million strong, pushed forward in a swing westward and then southward. It met stiff resistance from Belgian forts, and then was harried by stubborn French and British defensive action. As the German army moved west into Belgium, the French army moved east toward Alsace and Lorraine, provinces lost to Germany in 1871. German defenses held and inflicted massive casualties on the French. On one day, 24 August 1914, over 24 000 French soldiers died in action. This 'Battle of the Frontiers' was a massive defeat for the French. But the strength of their east–west rail links enabled the bulk of French forces to move west to meet the real threat of the German advance toward Paris. There, on the river Marne, the German thrust was stopped. The German army retreated northward and dug in on the river Aisne. When French and British forces pursuing the German army reached the Aisne, they were unable to move the invaders. There the 'Western Front' was born. It soon stretched from Belgium to Switzerland.

There is little doubt that the Battle of the Marne was a German catastrophe. The whole purpose of German strategy had failed. There would be a two-front war. By the end of 1914, the chief of staff of the German army, von Moltke, had been replaced by Erich von Falkenhayn. But what redressed the strategic balance was a massive German military victory on the Eastern front. Two columns of Russian troops advanced into East Prussia at the same time as the German army moved through Belgium and France. These columns were separated by a string of lakes. A German staff officer, Max Hoffmann, took advantage of the geography and of the existence of a north–south rail link. Under the cover of darkness, the German army in the north moved south. The Russian column in the north had no idea they were facing an empty landscape; the Russian column in the south had no idea they were facing a numerically superior force, that is, until they were annihilated at the Battle of Tannenberg. The commander of Russian forces in the south, Samsonov, committed suicide. The two commanders of the German forces, who had not planned the operation, but who reaped its rewards, became national heroes. They were Paul von Hindenburg and Eric Ludendorff (Showalter, 1991).

1915

The war spread in 1915, but the rough stalemate of 1914 remained unbroken. One major attempt to break it was in Turkey, then an ally of Germany. To "stop our troops from chewing on barbed wire" on the Western front, as Winston Churchill, Britain's First Lord of the Admiralty, put it, a plan was hatched to knock Turkey out of the war by a naval operation. The aim was to use British naval power to force the straits that connected the Mediterranean Sea to the Black Sea. Once done, the Turkish capital of Constantinople would be indefensible. The defeat of Germany's ally Turkey would serve many purposes. It would open supply lines to Russia; it would convince all and sundry, especially in the Islamic world, of the error of siding with Germany in the world war; it might even convince Germany to withdraw from France and Belgium.

Nothing of the sort happened. Here too, a mixture of arrogance, ignorance, and confusion ruled. The enemy was Oriental, and all the distortions attending Western attitudes toward the Orient flourished. The enemy was underestimated. Attempts to push a naval force through the Dardanelles failed in March 1915. The Allies decided to mount a joint land–sea operation, but no one had a clear idea of the terrain on which soldiers would land. When they went ashore on 24–25 April, they faced steep cliffs and stiff Turkish resistance. They never got off the beaches. A 6-month stalemate ensued, after which Allied forces withdrew (Prior, 2009).

1916

Two further attempts were made to shift the balance of power on the Western front. The first was at Verdun, in eastern France. There, on 21 February 1916, more than 1 million shells fell on French positions in the hills north of the garrison city of Verdun. The idea was to force the French into total defense of this relatively unimportant position. The French, Falkenhayn reasoned, valued Verdun as a symbol of French freedom and power (Afflerbach, 1994). He was right. The French committed 259 out of its full complement of 330 infantry regiments to the struggle for Verdun. They moved into Verdun along a vast conveyor belt, which the French called *la voie sacrée*, the sacred way. It certainly was a field of sacrifice. Falkenhayn succeeded in bleeding the French army white, but he did so at a massive cost to his own troops. Perhaps half a million men died at Verdun, where, by November, the French army had recaptured all the ground lost in the early days of the battle. Lasting 10 months, the Battle of Verdun was the longest battle in history. The front remained about where it had been before the bloodbath (Horne, 1962).

The same failure to break the stalemate occurred further to the north, where the British and French armies opened a major offensive on 1 July 1916. Here, the fault lay in an underestimate of the enemy's fortifications and an overestimate of the power of artillery to destroy them. A 1-week barrage by British guns was supposed to obliterate German defenses between Amiens and St Quentin in the lowlands of the Somme. But the deep dugouts under the German lines withstood the barrage, and when British forces moved out early in the morning of 1 July, they were mown down by German machine guns. Of the 100 000 men who went over the top, 60 000 were casualties, of whom 20 000 died in that single day. Thereafter, British and German forces regrouped. A further advance on 14 July was somewhat more successful, but by September, it was apparent that no breakthrough would take place. German lines held, but at a high price. German casualties numbered approximately 450 000; together French and British casualties surpassed 600 000. One million men fell, and the lines remained roughly where they had been at the beginning of 1916 (Keegan, 1976).

Stalemate was also the rule at sea, where the British fleet kept the German fleet penned up to the east of Denmark. One attempt to shift the war to the west at Jutland resulted in mixed fortunes for both navies. But the ultimate result was that the German high seas fleet was kept away from Britain.

1917

In 1917, the balance of power remained unchanged on the Western front. But in the east and in Italy, Germany and Austria were in the ascendant. First came the crisis in Russia. After the February revolution that toppled the Czar and put a provisional government in power, that government vowed to carry on the war. This was its worst mistake, made evident by a catastrophic offensive launched on 1 July 1917. When the Russian offensive failed, a counteroffensive produced a massive Russian retreat, which effectively destroyed the Russian army as a fighting force. When the Bolsheviks came to power in October, they saw what had to be done. They sued for peace, and signed an armistice on 3 December 1917. Germany and her allies had won the war on the Eastern front.

In Italy, the Allied cause suffered a series of alarming reverses. At Caporetto, the Italian army collapsed, and fled westward 100 km where a new defensive line was hastily formed. In France, a spring attempt to pierce German lines at the Chemin des Dames failed, and when the French commander Nivelle persisted in trying to do the 'undoable,' his army mutinied (Smith, 1994). Nivelle was replaced by Pétain; the offensive was called off; the anger of frontline troops abated. British attempts to shift the balance of power in Flanders were also unsuccessful, in part through the unhappy coincidence of their attack at Ypres occurring in the wettest summer on record. The British offensive, which ended in the rubble of the village of Passchendaele on 10 November 1917, literally drowned in mud (Prior and Wilson, 1996).

The German navy attempted to shift the balance of power by launching unrestricted submarine warfare in February 1917. This was a colossal miscalculation. It did not starve the United Kingdom into negotiating an armistice. Despite massive losses to British shipping, domestic food supplies remained adequate (Offer, 1991). What was worse from the German point of view was the provocation posed by naval attacks to the United States, which entered the war in April 1917.

1918

In January 1918, it would have been difficult for a neutral observer to predict Allied victory by the end of that year. How did it happen? First, the political and economic balance of power shifted with US entry into the war in 1917. Given the time needed to raise and then move an army of 2 million men across the Atlantic, it was apparent that US troops and US

supplies would directly enter the balance of power only in 1918. This gave the Allies a new and deep reservoir of men and materiel, which the Central Powers could not match. Thus, it was not US firepower that turned the tide, but US reserves.

This became apparent after the German army launched its last major military gamble of the war. On 21 March, 47 divisions of the German army broke through at the point where British and French forces met on the Western front. Finally, the Western front moved. Within a week, German forces had moved 40 miles (65 km) to the west. In April, they attacked at Ypres; in May and June to the south, reaching the Marne. But there the offensive broke down. The gamble had failed. The German army had lost 1 million men in a last, desperate, and futile effort to win the war (Keegan, 1999).

When German forces saw that they could not win, the balance of power shifted radically toward the Allies. Starting in early August, German troops began to surrender *en masse*. High Command was getting reports of low morale among troops, who were convinced that further sacrifices were in vain. At this point, unrest on the home front merged with despair over the military situation. The High Command saw that the game was up (Deist, 1991). At the same time, Austrian and Bulgarian positions crumbled. Ludendorff urged the kaiser to turn to the US President, Woodrow Wilson, to broker an Armistice. Ludendorff resigned. The kaiser fled to the Netherlands, leaving it to others to face a disaster he and his military had engineered. The Armistice came on 11 November 1918. The Great War was over.

Consequences

Demographic

Total casualties and losses as a proportion of those who served passed a threshold beyond previous experience. Wherever the threshold is, the total of roughly 9 million dead soldiers (according to varying estimates) is beyond it: this constitutes roughly one in eight of the men who served. Adding statistics on other casualties, it is apparent that roughly 50% of the men who served were either prisoners of war, wounded, or killed.

The most murderous theater of operations was the Eastern front, where disease and enemy action described the course of a nineteenth-century war waged with twentieth-century weapons. Of all Serbs who served in the war, 37% were killed; roughly one in four Rumanians, Turks, and Bulgarians also perished. On the Western Front, where the war was won and lost, combat was about half as lethal: German and French losses were about one in six of those who served; British losses were one in eight.

Initially, casualties among social elites were higher than among the rest of the population. The longer the war lasted, the greater was the democratization of loss. The reason is that officer casualties were higher than those in the ranks, and the social selection of the officer corps mirrored inequalities in prewar life. Consequently, in its initial phases, the higher up in the social scale a man was, the greater were his chances of becoming a casualty of war. By 1917, elites were sufficiently decimated to require the armies to draw junior officers from wider social groups, which in their turn suffered disproportionately higher casualties in the last 2 years of the war.

Among the poor and the underprivileged, the story is different. Prewar deprivation saved the lives of millions of working class men and poor peasants, whose stunted stature and diseases made it impossible for them to pass even the rudimentary standards of medical fitness for military service during the war. In the British case, roughly 35% of the men examined for military service were either unfit for combat or unfit to wear a uniform at all (Winter, 1985).

Numerically, workers and peasants formed the vast majority of the army of the dead. The same was true of disabled men, visible reminders of the war on street corners and in farming villages throughout the world.

More lethal than combat was a visitation of epidemic influenza, colloquially known as 'the Spanish flu.' In 1918 and 1919, this mutant virus killed young, healthy adults throughout the world. The war may have helped spread the disease, although it did not cause it.

Political

The Treaty of Paris, the peace settlement ending the Great War, was signed on 28 June 1919, 5 years to the day after the assassination of Franz Ferdinand in Sarajevo. Its major effects were to ratify the breakup of the Austro–Hungarian and Turkish empires, and to establish a new state system in Europe, wherein Germany was stripped of Alsace and Lorraine in the west and much of East Prussia in the east. Primary responsibility for the war and for making material reparations for it were laid at the feet of the new German Republic (Macmillan, 2002).

Through a League of Nations, international conflict would be regulated, if not resolved. An International Labour Organization was established to help address problems of working class life, a clear response to the Bolshevik revolution. The new Soviet Union was not a party to the peace negotiations or to the settlement. Instead, a kind of quarantine was applied to the Soviet Union, and tacit support was given by the victorious powers to modest military intervention in Russia on the side of the anti-Bolshevik forces. This intervention was a total failure.

While the principle of self-determination for all was established, colonial and imperial issues were resolved through bilateral talks among imperial powers. Thus, spheres of influence in the Middle East were divided between France and the United Kingdom, and contradictory promises were given to Arabs and Jews as to the future postcolonial disposition of the area. Anticolonial movements grew rapidly, and violent repression followed in Egypt, India, Korea, and China (Manela, 2007).

In short, the Great War set the terms of the international order for the rest of the twentieth century (Boemeke et al., 1998). Domestically, the political consequences of war were mixed. Socialist and labor parties had participated in government. Right wing nationalist groups also grew. Among them were fascist parties, whose elevation of the virtues of armed struggle was mixed with a hatred of the political left. The center of politics weakened, evidenced by the waning of support for Liberal parties. The polarized left–right divide took on violent form in Italy, Germany, and throughout Eastern Europe, mixing ideological and territorial conflicts in such a way as to ensure the outbreak of a new and more lethal world war in just 20 years.

The war opened a phase of domestic strife in which the upheaval of war was mixed with revolutionary struggles. Civil war in Russia lasted for 3 years after the Armistice; armed conflict continued in the new states of Poland and Hungary. The victorious Allies quarantined the new Soviet Union, and began a phase of cold warfare that lasted for 70 years. For this reason alone, some historians see the war as inaugurating the 'short twentieth century,' from 1914 to 1991 (Hobsbawm, 1995).

Economic and Social

The Great War was both the apogee and the beginning of the end of European domination of the world economy. The big loser was the United Kingdom, whose export economy suffered from import substitution in countries throughout the world who developed finished goods during the conflict, when British exports were unavailable. Chronic financial instability weakened London as a banking center. The era of free trade was over (Milward, 1984).

The losers paid for the war in a host of ways. Reparations were forced on Germany, although she managed to avoid paying most of the bill. Worse was the continuation and acceleration of wartime inflation into the postwar years, wiping out savings and deepening domestic social and political conflict in Germany and Austria (Feldman, 1993). This drastic reduction in the value of money had serious effects on the social structure and political outlook of middle class groups, threatened by proletarianization (Kocka, 1984).

Domestically, economies of scale were introduced during the war, which proved important after it. Hence, military conflict helped accelerate the movement away from the small family firm toward corporate economic life. State interest in and intervention in scientific research and education also expanded during and after war, in the light of evident strategic considerations (Hardach, 1987).

After the war, the state continued to play a greater role in economic life than ever before. This was not through the ownership of industry, but through the management of debt. In most industrialized countries, taxation levels doubled over the war decade, and much of it was spent servicing war debt. The United States was the exception here, turning because of the war from a debtor to a creditor nation, although the chronic weakness of countries indebted to it after the war, like the United Kingdom, helped turn the Wall Street crash of 1929 into the world depression.

Cultural

The cultural consequences of the Great War were evident in the politics of hatred, displacing violent conflict from the national enemy in the trenches to the class or racial enemy in the homeland itself. After 1918, Germany, Poland, Hungary, the Ukraine, Byellorussia, Turkey, Ireland, and Russia plunged into civil war (Audoin-Rouzeau and Becker, 2002).

In the 1920s, the League of Nations and pacifist veterans' organizations worked toward cultural demobilization. Their aim was to place the resort to war outside of the law. Their effort failed, and by the mid-1930s, Germany, Italy, and Japan geared up for war again.

Table 1 Some estimates of military losses among combatant countries in the 1914–18 war

					Total killed		
Country	*Total killed or died (in thousands)*	*Total mobilized*	*Prewar male population (aged 15–49 years)*	*Total prewar population*	*Per 1000 mobilized*	*Per 1000 males (aged 15–49 years)*	*Per 1000 people*

Source: Winter, J.M., 1985. The Great War and the British People. Macmillan, Basingstoke, UK.

Through its unprecedented human cost, the consequences of the Great War extended beyond the political sphere. Disabled veterans were visible on the streets of all combatant countries.

Every combatant country, every town, every village, mourned its war dead in public. The outcome is a vast array of war cemeteries near the fields of battle and of war memorials dotted in villages and towns throughout Europe, North America, Africa, Asia, and the Antipodes. Annual commemorative ceremonies were (and still are) held on 11 November (Winter, 1995) (Table 1).

The monumental character of the war indelibly marked the literature, poetry, and visual arts of the twentieth century (Cork, 1994; Fussell, 1977; Hynes, 1990). The Great War is the point of reference for much subsequent writing about catastrophe, and has introduced terminology – like shell shock – which has entered colloquial language. In many countries, although not in the former Soviet Union or the United States, its shadow is longer than that of the Second World War (Winter, 2009).

Abstract

Irving Fisher has been widely recognized as one of the greatest American scientific economists. He has been credited with being a primary architect of the 'pillars and arches' of modern economics – to borrow a phrase from J. A. Schumpeter – through his contributions to the theory of capital and interest, to monetary theory, and to the construction of index numbers. He was also an activist in promoting economic and social reforms. His reputation suffered during the 1930s when his approach to the discipline was eclipsed by Keynesianism. His accomplishments were then neglected and had to be rediscovered.

Irving Fisher is widely recognized as one of the greatest American scientific economists. He has been credited with being a primary architect of the 'pillars and arches' of modern economics – to borrow a phrase from J. A. Schumpeter – through his contributions to the theory of capital and interest, to monetary theory, and to the construction of index numbers. He was also an activist in the promotion of economic and social reforms. His reputation suffered in the 1930s when his approach to the discipline was eclipsed by Keynesianism. His accomplishments were then neglected and had to be rediscovered.

Beginnings

Irving Fisher was born on 27 February 1867 in Saugerties, New York and was the elder son of a Congregational clergyman. His was a home grown talent, nurtured in a single American institution: Yale University. Thus, unlike most American economists reaching professional maturity in the last decades of the nineteenth century, he had no direct exposure to the teachings of the German historical school. His intellectual development was shaped by two forceful members of Yale's faculty: Willard Gibbs, a mathematical physicist, and William Graham Sumner, a political economist who was also a champion of Social Darwinism. Their joint influence was observable in his choice of topic for a Ph.D. dissertation – *Mathematical Investigations in the Theory of Value and Prices*. With the publication of this exercise in general equilibrium theorizing in 1892, Fisher was hailed as a path breaker in mathematical economics. Fisher joined the Yale faculty in 1892 as an instructor in mathematics. In the following year, he married Margaret Hazard, a daughter of a wealthy Rhode Island textile manufacturer; their union was to produce two daughters and a son. In 1895, his appointment at Yale was shifted to the Department of Political Economy, an affiliation he retained until retirement in 1935. In 1898, he was promoted to full professor, but was soon diagnosed thereafter with a potentially fatal case of tuberculosis that idled him for the next 3 years. Upon recovery, he decided that the life of an ivory tower academician was no longer sufficient to satisfy him. Indeed he was convinced that scientific professionals had an obligation to engage with the world by promoting economic and social uplift.

Contributions to the Theory of Capital, Income, and Interest

Fisher had undertaken preliminary inquiries into the nature of capital before the interruption occasioned by illness. He returned to this theme in 1904 when his energies approached full restoration. Results emerged quickly in two major treatises.

In *The Nature of Capital and Income* (1906), Fisher set out a rigorous formulation of key concepts that had formerly been clouded by confusion. Capital (including human capital) was identified as the stock of assets that yield services, whereas income referred to the flow of services that generated satisfactions. He further demonstrated that the value of capital was determined by discounting the future income stream. This finding marked a distinct analytic advance. Though now generally accepted, Fisher's insistence that asset values were oriented toward the future, rather than to historical cost, was controversial when first presented. One feature of the book's argument has continued to be controversial, i.e., his claim that the correct concept of income should identify it with consumption spending and should exclude saving. *The Rate of Interest* (1907) was a logical sequel to *The Nature of Capital and Income*.

The earlier book had established the pivotal role of the interest rate in capitalizing the value of an anticipated income stream. It thus remained to demonstrate how the rate of interest was itself determined. When Fisher first addressed this issue, debate was polarized between two rival positions: one explanation of interest focused on increments in output arising from the use of capital (the technological school); a second emphasized the necessity to reward savers for deferring consumption (the psychological school). Fisher's initial analysis was centered on 'impatience' – or an unwillingness to forgo today's consumption without the prospect of greater consumption possibilities tomorrow – as the principal explanatory factor. When he returned to this topic in *The Theory of Interest* (1930), he argued that the technological and the psychological arguments were complementary, that is, that the interest rate was determined by the interaction between

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61033-4

'impatience to spend income and the opportunity to invest it.' The real interest rate was thus unambiguously a real phenomenon, not a monetary one. This line of analysis would stand in sharp contrast to the monetary theory of interest that Keynes was to offer in his *General Theory of Employment, Interest and Money* (1936). For Fisher, money still mattered because of its impact on the price level. It could thus affect the nominal interest rate, which Fisher treated as the real interest rate plus the inflation rate.

Early Work in Monetary Theory

The Purchasing Power of Money (1911) was conceived as an exercise in establishing the validity and usefulness of the quantity theory of money, a doctrine that had been politically contaminated in the polemics over 'free silver' in the 1890s. In Fisher's formulation, 'the equation of exchange' was written as $MV + M'V' = PT$. (In this expression, M represented the quantity of cash and V the velocity of its circulation; M' stood for total deposits subject to check and V' for the average velocity of their circulation; P was defined as an average price and T as the volume of trade.) This book was a vigorously monetarist document in which Fisher maintained that changes in the general price level were linked to proportionate changes in the money supply. This was true in the 'normal period,' defined as a state of equilibrium in which the values of T and the V′s were constant. His choice of terminology on this point bred misunderstandings: he recognized readily that economic reality was typified by 'transition periods' – when adjustments to disturbances were being worked out – in which the constancies did not hold.

Fisher was not content to offer solely an analytic explanation for variations in the purchasing power of money. Convinced as he was that monetary instability produced distributive injustices by distorting the relative positions of creditors and debtors, he felt obliged to suggest a corrective. His proposed remedy prescribed that changes in the general price level should be offset by variations in the gold content of the dollar (i.e., the 'compensated dollar' plan). But this policy recommendation did not mesh with the analysis presented in *The Purchasing Power of Money*. The 'compensated dollar' scheme rested essentially on a 'commodity theory of money' in which the real value of money was determined by the value of its gold equivalent. This conclusion did not follow from the 'equation of exchange' that Fisher had set out as the basis for his 'quantity theory of money.' Schumpeter (1948) and Patinkin (1993) have suggested that this oddity can be explained because Fisher, the reformer, got the better of Fisher, the scholar.

Analytic Innovations in the 1920s

Given Fisher's concern for stabilization of the general price level, his interest in perfecting the instrument for measuring its behavior – namely, the index number – was readily comprehensible. He addressed this in *The Making of Index Numbers* (1922), a work which has continued to be influential. Shortly thereafter, he created an Index Number Institute (INI) that provided weekly reports on leading economic indicators, along with commentary on current events. These analyses were distributed nationally via a syndicated news service. At its peak, Fisher's INI column had a potential to reach about 7 million readers.

By the mid-1920s, Fisher's studies had convinced him that the stakes in price level instability were higher than he had earlier thought them to be. When writing *The Purchasing Power of Money*, he regarded distributive injustices as the major evil associated with unstable prices. His later analyses indicated that instability of the general price level was responsible for another major problem – fluctuation in the volume of trade and, with it, variations in aggregate income and employment. This conclusion, he maintained, was supported by statistical evidence indicating that the rate of change in the general price level was highly correlated with variation in the volume of trade. This relationship, however, was not instantaneous.

His empirical investigations suggested a lag of approximately 7 months between the turning point in the rate of change in prices and change in aggregate economic activity. In this research, Fisher introduced a novel statistical technique – the distributed lag – which has become a standard tool in econometrics. With its aid, his results appeared to show conclusively that a rising price level stimulated trade, while a falling price level depressed it. It thus followed that the way to eliminate macroeconomic fluctuations was to maintain a stable price level. In that spirit, the Fisher of the mid-1920s wrote that the 'so-called business cycle' was really 'a dance of the dollar' and that there was no reason why such disturbances should be tolerated.

Crusading for Causes

Fisher, the recovered TB patient, was an indefatigable champion of causes. This was evident in his tireless promotion of monetary reforms: in the first instance, in lobbying for a 'compensated dollar' that promised to stabilize the dollar's purchasing power. In the 1920s, he lobbied vigorously for legislation that would compel the Federal Reserve to maintain price level stability. His views by then had changed on how this should be accomplished. In 1923, with the discovery of the potency of 'open market operations' – a technique for altering commercial bank reserves through the purchase or sale of government securities by the Federal Reserve system – Fisher readily embraced this procedure as the major instrument for central bank control of the money supply. He was a frequent visitor to Washington as a star witness before Congressional committees with jurisdiction over monetary affairs. He also poured considerable energy into mobilizing public opinion behind reform proposals through the creation of organizations such as the Stable Money League.

Fisher's reformist agenda was not restricted to matters directly linked to his expertise as an economist. He was an enthusiast for measures to improve the health and longevity of the population. On his initiative, a group of leading citizens was organized in 1907 to lobby – unsuccessfully as it turned out – for the creation of a Federal Department of Health that would establish national standards for public health practices and monitor their enforcement. He enjoyed greater success in

the promotion of a Life Extension Institute to persuade life insurance companies that it would be profitable to require and pay for annual physical examinations for policy holders. To reinforce its activities, he co-authored a first-of-its-kind manual of good health practices, entitled *How to Live*, that went through some 21 editions.

Fisher was one of the nation's staunchest advocates of national prohibition of the consumption and sale of alcoholic beverages. Once the 18th amendment to the Constitution (1920) had been enacted for that purpose, he was a leading voice in arguing against its repeal. Even though enforcement of prohibition left much to be desired, he maintained that this legal ban had still contributed positively to American economic expansion in the 'new era' of the 1920s through its effect on improved worker efficiency and on reduced workplace absenteeism. This line of thinking was responsible, in part, for his disastrous misreading of economic conditions in the autumn of 1929 when he predicted that the American economy was on the threshold of permanent prosperity. In the 1920s, he was also an inveterate campaigner for an international organization to promote world peace and for membership of the US in the League of Nations. He was a prominent figure as well in the eugenics movement that he hoped would encourage state governments to enact legislation permitting sterilization of the mentally defective and the criminally insane.

Fisher contributed significantly from his own pocket to support these causes. His ability to do so was enhanced by the sale of one of his inventions – an Index Visible filing system – to Rand-Kardex (shortly to become Remington Rand) for a handsome block of stock and for a position on the board of directors. When informing his son about this turn of fortune, he wrote: 'This added income will enable me to further the four chief causes which we have at heart, the abolition of war, disease, degeneracy, and instability of money (Fisher to Irving Norton Fisher, 17 June 1925).

Coping with the Disaster of Depression in the 1930s

Fisher was totally caught off-guard by the collapse of the stock market in the autumn of 1929 and by the events that followed. His personal financial circumstances were left in shambles: he managed to avert personal bankruptcy only by borrowing heavily from his wife's unmarried sister. The Great Depression was also a professional embarrassment. It did stimulate him to rethink where his earlier line of analysis had failed him. The result – reported in *Booms and Depressions* (1932) – was the debt-deflation theory of Great Depressions. The problem, as he then saw it, stemmed from a situation of overindebtedness in the late 1920s. Once a break in the price level had occurred, the real burden of debt increased. This led to distress selling, to contraction in deposit currency, and to slackening in the velocity of monetary circulation. Deflation – far from being self-correcting – simply bred more deflation. The remedy was implicit in the diagnosis: 'reflation' of the price level to its elevation at the time when most outstanding debts were contracted. When that point had been reached, the general price level should be stabilized.

To accomplish this, Fisher urged a number of proposals on the Roosevelt administration. For example, he endorsed 'stamped scrip' – a scheme which called for a special currency issue that would lose 2% of its value each week unless a two-cent stamp were affixed to it. This device (which he had borrowed from Gesell) was intended to accelerate the velocity of monetary circulation. Though the idea was not original with him, he later put his full weight behind advocacy of a plan that would require commercial banks to hold '100 percent reserves' against demand deposits, thereby eliminating their capacity to create (or destroy) check-book money by extending (or calling) loans. The money supply would instead be controlled by a public authority (e.g., a Currency Commission) that would expand the money supply as needed to achieve a prescribed 'reflation' target and thereafter to stabilize. Fisher's conception of a 'monetary rule' was tied to outcomes, as opposed to the 'rule' recommended in Milton Friedman's brand of monetarism that stipulates a fixed rate of growth in the money supply.

Fisher's thinking about recovery from the Great Depression always had a monetary orientation. He was unsympathetic toward fiscal stimulants – such as Keynesian-style programs of public works – and he made no secret about that. He was also unsympathetic to the analytic message of Keynes's *General Theory*. Even so, he and Keynes came close to convergence in their recommendations for tax policy in wartime: both championed a tax targeting consumption. The analytic props to their conclusions, however, had nothing in common. Fisher's views – which he spelled out in his final book, *Constructive Income Taxation* (1942) – rested on the analysis he had worked out in 1906 in *The Nature of Capital and Income*. This argument maintained that income should properly be defined as expenditure on consumption: thus, a sound tax system, in all circumstances, should take aim at consumption spending. Keynes's position, on the other hand, was informed by his conception of the management of the components of aggregate demand, as formulated in *The General Theory*.

Despite the fact that the Roosevelt administration took little heed of his unsolicited advice, Fisher still believed that something hopeful could be salvaged from the wreckage of depression in the form of lasting improvement in scientific investigation in economics. It had long been his aspiration to build an international organization to bring economists interested in linking economic theory with mathematics and statistics into closer collaboration. Circumstances of the early 1930s permitted this dream to become a reality. The presence at Yale in 1930 of Ragnar Frisch of the University of Oslo made it easier for three who shared the dream – Fisher, Frisch, and C. F. Roos – to lay the groundwork for the Econometric Society. The obvious shortcomings of economic forecasting in the early depression years – and an apparent need for improvement – convinced a well-to-do businessman to underwrite this new organization.

A Word about the Legacy

Fisher was accorded numerous honors by professional colleagues: among them, election to the presidencies of the American Economic Association, the American Statistical

Association, the Econometric Society, the American Association for Labor Legislation. But he lacked a committed cadre of disciples: there was no 'Yale circus' to match Keynes's 'Cambridge circus.' In the last decade of his life, his approach was largely overshadowed by Keynesianism. To younger members of the profession, he appeared to be out-of-step with the times, with the consequence that his work tended to be ignored.

With the waning of the Keynesian ascendancy, Fisher's achievements have been revisited. His pioneering analyses of capital and interest have now approached the status of an orthodoxy in the graduate training of prospective professionals. A 'rediscovery' in the 1970s documented that an article he wrote in 1926 – entitled *A Statistical Relation between Unemployment and Price Changes* – anticipated the essential insight of the Phillips Curve by more than three decades. It is interesting to speculate on how the principals in an intense controversy that divided the profession in the 1960s and 1970s would have behaved had they known that Fisher had identified the 'reswitching problem' in 1907.

In the 1990s, some of Fisher's practical proposals have enjoyed a renewed lease on life. In 1997, the US Treasury issued a 'stabilized bond,' the return on which would be adjusted to maintain constancy in its purchasing power. Fisher had advocated the creation of this type of financial instrument some seven decades earlier. In 1995, the US Department of Commerce resurrected another Fisher conception, dating from 1922, when adopting his formula for an 'ideal index number' to calculate the GNP deflator.

Fisher died on 29 April 1947 in New York City.

Abstract

R.A. Fisher was one of the great intellects of the twentieth century. His contributions to evolutionary theory and mathematical genetics ensure him a place in the Darwinian pantheon. He is the undisputed father of modern statistical theory, standing alongside his great predecessors Gauss and Laplace. His statistical methodology has had a far-reaching impact whether one considers the mathematical theory of distributions, the design and analysis of experiments, the theory of estimation, the theory of significance testing, or the logic of statistical inference. In genetics he was the principal architect of the application of statistics, much of his general theory having been inspired by practical problems, especially in human genetics.

Sir Ronald Fisher, the father of modern statistics, was for most of his working life a professor of genetics, first in London and then at Cambridge. He made lasting contributions to mathematical and evolutionary genetics as well as to statistical theory. In statistics his contributions stand alongside those of his great predecessors Gauss and Laplace, while in evolutionary theory he is acknowledged as the greatest of Darwin's successors.

Fisher was born in London on 17 February 1890, the son of George Fisher, a fine-art auctioneer, and his wife Katie. His twin brother was stillborn. At Harrow School, which he entered in 1904 as a scholar, he distinguished himself in mathematics despite being handicapped by poor eyesight, which prevented him working by artificial light. His teachers used to instruct him by ear, and Fisher developed a remarkable capacity for pursuing complex mathematical arguments in his head. This manifested itself later in life in an ability to reach a conclusion while forgetting the argument, to handle complex geometrical trains of thought, and to develop and report essentially mathematical arguments in English (only for students to have to reconstruct the mathematics later). Fisher's early interest in natural history was reflected in the books chosen for special school prizes at Harrow, culminating in his last year in the choice of the complete works of Charles Darwin in 13 volumes. Fisher entered Gonville and Caius College, Cambridge, as a scholar in 1909, graduating BA in mathematics in 1912. At college he instigated the formation of a Cambridge University Eugenics Society through which he met Major Leonard Darwin, Charles's fourth son and president of the Eugenics Education Society of London, who was to become his mentor and friend. He spent a postgraduate year in the Cavendish Laboratory, Cambridge, studying the theory of errors under F.J.M. Stratton and statistical mechanics and quantum theory under J.H. Jeans (later Sir James Jeans).

Prevented from entering war service in 1914 by his poor eyesight, Fisher taught physics and mathematics in schools for the duration of the war and in 1919 was appointed a Statistician to Rothamsted Experimental Station, an agricultural station at Harpenden north of London. In 1933 he was elected to succeed Karl Pearson as Galton Professor of Eugenics (i.e., of Human Genetics, as it later became) at University College, London, and in 1943 he was elected as Arthur Balfour Professor of Genetics at Cambridge and a Fellow of Gonville and Caius College, succeeding R.C. Punnett. After he retired in 1957, Fisher traveled widely, spending his last few years in Adelaide, Australia, as an honorary research fellow of the Commonwealth Scientific and Industrial Research Organisation (CSIRO) Division of Mathematical Statistics. He died there of a postoperative embolism on 29 July 1962. His ashes lie under a plaque in a side aisle of Adelaide Cathedral.

Fisher married Ruth Eileen Guinness in 1917 and they had two sons and six daughters, and a baby girl who died young. He was elected a Fellow of the Royal Society of London in 1929 (as a mathematician) and was created Knight Bachelor by Queen Elizabeth II in 1952 for services to science. He was the founding President of the Biometric Society (now the International Biometric Society) in 1947, and served as President of the Royal Statistical Society (of the UK), of the International Statistical Institute, of the Genetical Society of Great Britain, and of his Cambridge college, Gonville and Caius. He received many honorary degrees and accepted the honorary membership of many academies at home and abroad, and was awarded all the principal medals of the Royal Society, the Royal (1938), Darwin (1948), and Copley (1956).

Fisher's first publication, while still an undergraduate, proposed the method of maximum likelihood for statistical estimation (though not in those words) and before graduating he had already given an article remarking on the surprisingly good fit of Mendel's data. In 1916, without any academic appointment but encouraged by Leonard Darwin, he completed the founding article of biometrical genetics "The correlation between relatives on the supposition of Mendelian inheritance" (1918), eventually published in 1918 after it had been withdrawn following unfavorable reviews for the *Philosophical Transactions of the Royal Society* by Karl Pearson and R.C. Punnett (both of whom he later succeeded, as he was fond of remarking). In this article, Fisher introduced the word 'variance' and established the basis of the analysis of variance.

From his post of statistician at Rothamsted, Fisher made advances which revolutionized statistics, while his advances in genetics and evolution were hardly less path breaking. In a single publication in 1922 he proved that heterozygotic advantage gives rise to a stable gene-frequency equilibrium, introduced the first stochastic model into genetics (a branching process), and initiated the study of gene-frequency distributions by means of the diffusion approximation, and in another

article he applied the method of maximum likelihood for the first time, to the estimation of linkage.

Also in 1922, building on his method of maximum likelihood, Fisher published 'On the mathematical foundations of theoretical statistics' in the *Philosophical Transactions* (1922a), a revolution in statistical thought. This time the Royal Society's referees, A.S. Eddington and G.U. Yule, were more complimentary. Among the new words and phrases Fisher introduced in the article in order to clarify the basis of his approaches to statistical inference are likelihood, consistency, degrees of freedom, efficiency, sufficiency, information, significance level, test of significance, sampling distribution, percentage point, statistic, and others of a more technical nature still. Information in Fisher's statistical sense (1925a) antedated Shannon's (1948) use of the word for a somewhat different purpose: Fisher's information measures the content of a message, whereas Shannon's measures the ability of a channel to transmit a message, independently of its meaning. In 1930, Fisher published the first satisfactory account of what J. Neyman was later to call the 'confidence' property of interval estimation.

In distribution theory Fisher built on his 1915 article deriving the exact distribution of the correlation coefficient (for whose solution he introduced the concept of a sample-space) and used his considerable mathematical ability to solve many further distributional problems, including that of the multiple correlation coefficient and the variance ratio (which G.W. Snedecor of Iowa State University, where Fisher was visiting professor in 1931 and 1936, called 'F' in his honor). His work at Rothamsted on agricultural statistics soon led to the creation of the science of experimental design with the appreciation of the fundamental role of randomization, the development of the principles of blocking and confounding, and the introduction of Latin squares and factorial analysis and similar designs chosen for their statistical efficiency. The methods which Fisher invented or improved were brought together in 1925 in his book *Statistical Methods for Research Workers* (1925b), which he updated continually over the next 23 years until the thirteenth edition was published in 1958 (a posthumous fourteenth edition was prepared from notes written before his death).

In addition to the statistical work associated with his employment at Rothamsted, Fisher pursued his interest in evolutionary theory, guided and encouraged by Leonard Darwin. Putting his deep knowledge of Mendelian theory and Charles Darwin's writings to good use he built on the success of his earlier investigations of 1918 and 1922 to write *The Genetical Theory of Natural Selection* (1930), published in 1930. This book is now seen as the chief document of the 'Neo-Darwinian revolution,' that revival of Darwinism in the 1930s and 1940s from the neglect it had suffered in the early years of the century following the rediscovery of Mendel's article in 1900. The book contains a wealth of new evolutionary arguments, from the fundamental theorem of natural selection to ideas about sexual selection, inclusive fitness and parental expenditure. More than any other work *The Genetical Theory* established a firm basis for the modern view that evolution by natural selection is primarily a within-species phenomenon.

Taking up his appointment as Galton Professor of Eugenics at University College London in 1933, Fisher's pace did not slacken. Now able to pursue experimental work, which previously he had only undertaken in a private capacity, he demonstrated his ability as a natural historian. Experimental organisms included mice, poultry, and the purple loosestrife, and even dogs (under the auspices of the Genetical Society). In a long collaboration with E.B. Ford of Oxford he studied natural populations for the purpose of estimating the power of natural selection, thus contributing to the foundation of a school of ecological genetics. But it is in human genetics that he made his most lasting contribution of this period. In 1935 he secured funds from the Rockefeller Foundation to establish a Blood-Group Serum Unit at the Galton Laboratory with the express purpose of initiating the construction of a linkage map of man, for he had already seen the connection between 'Linkage studies and the prognosis of hereditary ailments' (to use the title of his lecture to the International Congress on Life Assurance Medicine in that year). Here is to be found the intellectual origin of the Human Genome Project. At the same time Fisher, with J.B.S. Haldane and L.S. Penrose, was advancing the special statistical theory required in the estimation of human linkage.

Fisher (1935) also saw the publication of *The Design of Experiments* in which his pioneering work in that subject at Rothamsted was expounded fully for the benefit of workers in agriculture and many other fields. Like *Statistical Methods for Research Workers*, the book was an outstanding success, running to seven editions by 1960 (an eighth was later prepared from notes left by Fisher). It opened with a famous description, often quoted, of an experimental design for the problem of testing the assertion of a lady who maintained that she could tell by tasting a cup of tea whether the milk or the tea had been the first to be poured into the cup. In the course of this discussion Fisher coined the phrase "null hypothesis" for the hypothesis under test.

In 1936, Fisher subjected Mendel's published data on segregation in the garden pea to close statistical scrutiny, concluding that in some respects the data seemed to follow too closely the expectations on Mendel's genetic hypothesis, a discovery that worried him greatly, and left him speculating that perhaps Mendel's assistant, knowing full well what his master hoped to find, was tempted to adjust some of the counts accordingly.

In 1943, Fisher moved to Cambridge as Arthur Balfour Professor of Genetics, where he was reunited with his colleagues from the Blood-Group Unit which had been evacuated there during the war. An immediate consequence was his brilliant solution of the Rhesus blood-group puzzle, involving three closely linked loci which between them explained the array of serological reactions which to everyone else had appeared chaotic: Fisher did for Rhesus what Mendel did for round and wrinkled.

After the Second World War ended in 1945 Fisher attempted to establish bacterial genetics in his Cambridge department and to retain for Cambridge the Blood-Group Unit, but without success. Work in his small department revolved around linkage in the mouse and studies on purple loosestrife, wood sorrel, and primroses, always with a strong background of mathematics and statistics. His *Theory of Inbreeding* (1949) was published in 1949, and in 1950 he published the first article applying a computer to a biological problem.

In the subject of statistics, developments in the United States during and after the war had tended to obscure the great advances which Fisher had made in the subject, and he found himself having to defend many of his views against critics brought up in the more mathematical and operational climate than dominant. His repeated insistence that statistical inference was a mode of reasoning separate from, though related to, approaches based on decision theory and other behavioral considerations won him few friends, and his continued (if somewhat puzzled) defense of his troublesome 1930 concept of fiducial probability was cited as evidence that his judgment was fallible. He defended his position in a fourth book, *Statistical Methods and Scientific Inference* (1956), published in 1956 with a second edition in 1959 and a posthumous edition with many additions and clarifications. In this work he particularly emphasized the direct role of likelihood in statistical inference, in addition to the method of maximum likelihood, and continued his life-long criticism of the improper use, as he saw it, of prior probabilities and Bayes's theorem in statistical inference, a methodology previously called 'inverse probability' for which he had himself coined the word "Bayesian" in 1950.

As well as writing his books, Fisher collaborated with Frank Yates, also of Rothamsted, to produce the most widely used compilation of statistical tables (before computers rendered such volumes redundant). First published in 1938, *Statistical Tables for Biological, Agricultural, and Medical Research* (1938) went through many editions.

In retirement Fisher continued his academic work, but also became embroiled in a controversy as to the extent to which the published data supported the hypothesis, then novel, that cigarette-smoking was a cause of lung cancer. Perhaps not fully appreciating the strong feelings which the issue was to generate, he focused on the finer points of the statistical analysis which interested him, on the need always to disentangle causation and correlation, and on the fact that the evidence did not seem to him to disallow the possibility that genetical variability might be a contributory factor in the observed association.

Fisher's articles number nearly 300, and he also wrote many reviews, particularly in *The Eugenics Review* between 1915 and 1935, and letters to journals. He was an accomplished formal lecturer as may be seen from his many presidential and similar addresses, and an occasional broadcaster on scientific topics. His interests were wide, as may be instanced from two examples from his publications: in 1934 he discovered and published the idea of a randomized or 'mixed' strategy independently of von Neumann, and in 1958 he published the first suggestion that the theory of games might be applied profitably to problems in evolutionary biology, the possibility having been drawn to his attention by Dr Cavalli (later Professor L.L. Cavalli-Sforza).

Small of stature, with thick glasses and a beard, Fisher did not suffer fools gladly. He was a skilled controversialist in conversation, but his quick temper sometimes rendered further discussion impossible. His contemporaries divided rather cleanly into those who regarded him with awe and affection and gratitude for the generosity with which he offered his ideas to them, and those who found him tetchy, difficult, and remote. Especially as a professor at Cambridge, he showed great interest in the few students who passed through his small department, and he always enjoyed the company of young people. Of the many thumb-nail sketches which his greatness has inspired, perhaps the following comment on Fisher by the Cambridge cosmologist Sir Fred Hoyle contains the closest likeness in the smallest span: "I am genuinely sorry for scientists of the younger generation who never knew Fisher personally. So long as you avoided a handful of subjects like inverse probability that would turn Fisher in the briefest possible moment from extreme urbanity into a boiling cauldron of wrath, you got by with little worse than a thick head from the port which he, like the Cambridge mathematician J.E. Littlewood, loved to drink in the evening. And on the credit side you gained a cherished memory of English spoken in a Shakespearean style and delivered in the manner of a Spanish grandee" (Hoyle, 1999).

Fisher was one of the great intellects of the twentieth century. His contributions to evolutionary theory and mathematical genetics ensure him a place in the Darwinian pantheon while he is the undisputed father of modern statistical theory.

The statistical methodology he developed has had a far-reaching impact in every field of science and social science. Whether one considers the mathematical theory of distributions, the design and analysis of experiments, the theory of estimation, the theory of significance testing, or the logic of statistical inference, Fisher's is the primary influence. As a teacher of research workers through his statistical books he had no peer.

In genetics he was the principal architect of the application of statistics, much of his theory having been inspired by practical problems, especially in human genetics. With J.B.S. Haldane and others he initiated the study of linkage in man specifically for the purpose of throwing light on hereditary disease risks, thus foreshadowing the human genome project, and he encouraged the study of associations between blood groups and disease. His studies on natural and artificial populations of both plants and animals would alone have given him an honored place in the development of genetics in the twentieth century. His '1918 paper' is accepted as the starting point for the entire development of biometrical genetics, with its ramifications in plant and animal breeding.

In evolutionary biology, his book *The Genetical Theory of Natural Selection* (1930) hides a brilliant series of evolutionary insights behind a density of writing that requires more concentration than most readers have been prepared to give it, but is now acclaimed as the cornerstone of the neo-Darwinian revival of the mid-twentieth century.

Abstract

This article discusses the place of fishing activities and coastal economies in social scientific thought, some of the major issues developed in the relevant literature, and recent trends in maritime anthropology; the category of fishing; natural and social models of fishing activities and coastal communities; gender relations; ecological knowledge; resource management; and the revitalized ocean.

The Category of 'Fishing'

According to some of the evolutionary theories of the nineteenth century, fishing represented a separate and early stage in the history of humans. Such an idea was underlined in many contemporary accounts of particular groups of people largely dependent on fish. The evidence on the role of early fishing, however, is fairly limited. Some scholars suggest that, from the point of view of early humans, aquatic environments must have been both hostile and an inadequate source of food. Others suggest that coastal zones must have been quite attractive, providing a worthwhile challenge, and that people may have exploited them for a long time without leaving modern groundlings any evidence. While the archaeological evidence does not indicate that fishing predated the hunting of terrestrial animals, nonetheless among hunter-gatherers fishing may have played quite an important role.

The abundance of resources in coastal zones may, indeed, have provided an opportunity for the development of complex civilizations. There is evidence for a transformation of hunter-gatherer social relations in coastal regimes, although many of the important issues involved are far from settled. Rather than seeing aquatic resources themselves as determinants of complexity, however, one should regard coastal niches as just one possible avenue for intensification (Kelly, 1992). With the advent of fieldwork and participant observation, evolutionary speculations tended to be replaced by descriptive accounts. The category of 'fishing' became much less visible than before – sometimes being subsumed under the label 'hunting and gathering.'

While the category of fishing may seem straight forward, it need not be taken for granted. The distinctiveness of fishing activities, it has been argued (Hewes, 1948), has two aspects. First, objects behave in a particular manner while in an aquatic substance, due to special conditions of buoyancy, turbulence, solubility, and refraction of light. Second, fishers and their prey occupy different media. An emphasis on differences in habitat yields a definition of fishing as "that category of human activity which is connected with the capture or gathering of animals (or plants) that regularly dwell in the water" (Hewes, 1948). The concept of fishing as a particular kind of hunting, which happens to yield fish is one element of a common anthropological scheme for classifying types of subsistence: gathering, collecting, hunting (including trapping), husbandry (including fish farming), and plant cultivation. Much like medieval Europeans who often distinguished between fishing, fowling, and hunting, modern anthropology tends to operate with three concepts of foraging – fishing, gathering, and hunting.

Some linguistic evidence suggests that fishing and hunting are perceived as similar strategies, differing only with respect to the focus of subsistence efforts. Indigenous terminologies, however, do not necessarily distinguish between hunting and other subsistence activities, including trapping, collecting, and gathering. Also, the classification of aquatic organisms, including 'fish,' varies from one society to another. Although in many societies, fish are classified according to an elaborate taxonomy, depending on their shape and usefulness to humans, the category of 'fish' represents one of the largest and most diverse categories found in most environments; at times fish terms are extended to all creatures inhabiting aquatic environments, including turtles, frogs, crocodiles, crustacea, and fish-shaped mammals. In some languages, there is no term for fish; fish are included in a heterogeneous category along with snakes, worms, lizards, and other elongated creatures.

Natural and Social Models

Many approaches to fisheries, both of the present and the past, suggest a 'natural' model of fishing, emphasizing material context and ecological relations. Social scientists have often drawn attention to the fact that fishing takes place in a relatively uncertain environment (Palsson, 1991). People who adapt to earning a living by exploiting marine resources, it is argued, often seem to manage their lives in similar ways. Thus, crew organization tends to be flexible and based more on voluntary ties than kinship obligations, to ensure cooperation and the right combination of skills, to reduce uncertainty, and spread the risks of production. Fishing societies, as a result, seem to have a range of characteristics in common due to the fact that their members have to adapt to the corresponding environments and cope with identical problems. Such approaches are reminiscent of the method of cultural ecology, according to which social life is rather mechanistically adapted to the material world.

In line with the assumptions of the natural model of fishing, there has been a strong tendency to look for parallels between trawling (industrial hunting) and small-scale fishing on the basis of a common link to water. While focusing on the

boundary between land and water is helpful for drawing contrasts between economic and social systems that are organized in similar ways, between aquatic and terrestrial industrial systems, much recent research has emphasized that a unitary category of fishing diverts attention from important issues, in particular, the social relations in which production is necessarily to be found. Although there are real empirical differences between fishing and other modes of subsistence, the use of such differences gives misplaced importance to ecology.

One way to understand similarities and differences among fishing systems, to emphasize the social context of production, is to distinguish between societies in terms of mode of circulation – the motivation of the producers and the destination of the products. Production may be primarily for exchange or use. Many fisheries conflicts derive from the different rationales of production of the household economy of local small-scale fishing and the market economy of industrial fleets (McGoodwin, 1990). Another way to distinguish fishing systems is to underline different forms of managing access to fish. While knowledge of ecology and fishing techniques is important for the understanding of different forms of managing access, one should not ignore the social space in which they occur. The informal exclusion of outsiders by means of secrecy and formal ownership of local territories should not be regarded as functionally equivalent devices. Differences among fishing economies in terms of modes of circulation of products and access to resources insufficiently represent the variety of production systems that exist. On the other hand, they help to illustrate the fundamental point that fisheries are embedded in social life. Any study of what happens on board fishing vessels must consider variations in fishing systems and the larger contexts of fisheries and fishing communities.

Gender Roles and Identities

In removing 'fishing' from the context of social relations, social scientists have often failed to recognize the importance of the relations of men and women and the significant economic role of women in fishing economies. The issue of gender tends to be suppressed or distorted. Nevertheless, in recent years an extensive literature on the role of gender in fishing and coastal communities has been developed (Nadel-Klein and Davis, 1988). In fishing communities, it has sometimes been suggested, one can expect a sharp division of labor along gender lines in which men do the fishing while women are responsible for the processing of the catch. A rigid sexual division of labor should not, however, be regarded as inevitable. In many cases, women's participation in extraction is no less important than that of men. The ethnography of fishing is biased with respect to gender. This observer's bias is partly a reflection of the popular Western image of fishing as a particularly 'manly' activity. Thus, the pursuit of small aquatic animals has sometimes been regarded as mere 'gathering' or 'collecting' if performed by women, but as 'fishing' if performed by men.

Many indigenous accounts of fishing economies are no less gender specific than observers' accounts, treating women's labor as not only different but also somehow secondary to that of men. While the devaluation of women's work is not restricted to market economies, the change from a subsistence economy to markets often has important implications for the social construction of gender. The 'domestic' labor of women tends to be presented as private labor, on the grounds that it takes place internal to the household and that its consumption products are 'perishable' use values, requiring immediate use. Conversely, only the nondomestic work of men is regarded as socialized since it alone involves cooperation between households, the production of exchange values, and durable commodities. Domestic laborers are presented as natural beings outside the social life of the market economy. And women only become social or visible insiders to the extent that they engage in nondomestic production, outside the sphere of reproduction. Women, then, tend to be presented as unproductive (Cole, 1991).

Just as extraction is a social activity whether or not it takes place in a group or by isolated individuals, labor is necessarily a social activity whether or not it takes place in a domestic or nondomestic context. The household is not a private place devoid of social content but a social institution constituted by a particular set of relations – the social relations of domestic production involved in the creation of use values, particularly cooking and child care.

Ecological Knowledge

Since fish are relatively incapable of coping with human predators, their chances of using evasive tactics are small. The difference in medium, however, has contradictory implications and some observers have emphasized the disadvantages to fishers, pointing out that if humans are invisible to the fish so are fish to humans. Accordingly, it is argued, knowledge of marine organisms is likely to be relatively restricted. Nevertheless, as several ethnographic accounts have shown, in fishing communities, people accumulate a vast amount of knowledge of fish and aquatic habitats. The social distribution and nature of ecological knowledge and its importance for resource management, on the other hand, are matters of some debate.

In fisheries generally, catches vary from one boat to another. Accounts of and interest in such differences vary from one context to another depending on the nature of the social system involved and the nature of the fishery. Some explanations emphasize differences in luck, others underline personal differences in fishing skill. Anthropological studies of fishing success have drawn attention to the continuity of the social world to which the skipper belongs, focusing on the importance of the crew for decision making and, by extension, relative fishing success. In a very real sense, the practical skills of fishing skippers are the result of mutual enskillment, the collective property of a community of practice (Palsson, 1994).

Not only has there been a growing theoretical interest in the practical learning of fishers and the general divide between indigenous and scientific knowledge, but also fisheries science itself is increasingly seen as an embedded enterprise (Smith, 1996). Some scholars argue that learning, whether in science or everyday life, primarily takes place with the internalization of a cognitive scheme. Others have emphasized that learning

involves the whole person interacting with the social and natural environment (Lave, 1990).

In many fishing societies, there is little attempt to draw upon the knowledge that practitioners have achieved in the course of their work for the purpose of marine ecological research. Analyses of human–environmental relations are the privileged task of people formally trained in public institutions. A greater reliance on practical knowledge, however, is a practical necessity, given the randomness and complexity of many marine ecosystems. Multispecies marine ecosystems, in particular, are highly unpredictable, with constant fluctuations in interactions among species and between species and their habitat (Acheson and Wilson, 1996). This does not mean that governance is impossible; it suggests, however, increasing reliance on a finer spatial and temporal scale of observation and engagement – a scale that only the skillful practitioner is able to apply. There are good grounds, therefore, for exploring how fishers acquire knowledge about the ecosystem within which they operate, how their knowledge differs from that of professional biologists, and to what extent the former could be brought more systematically into the process of management for the purpose of ensuring sustainability.

Resource Management

Many fisheries are currently in a state of crisis. Increasingly social scientists are addressing the problems involved, both internationally and in particular ethnographic contexts (McCay and Acheson, 1987). Two main positions can be identified, the market approach, which gained momentum in the early 1970s, and the approach of comanagement, which has received increased attention since the 1980s. Comparative studies of the implications and consequences of different management regimes represent an important and growing forum for social research.

The market approach assumes that the crises in fishing are due to the open access nature of fisheries; in the absence of both government control and the institution of private property, it is assumed, people will inevitably drive the ecosystem beyond its sustainable limits. The paradigm further suggests that only the 'hidden' forces of the market can ensure efficiency and sustainable use of resources. Finally, the issues of ethics and equity typically are presented as irrelevant theoretical distractions. In several fisheries in different parts of the world, fishing stocks are being turned into private property. First, the resource is appropriated by regional or national authorities and later on the total allowable catch for a season is divided into quota holdings and allocated to producers, often the owners of boats. At a still later stage, the temporary privileges of quota holders are turned into a marketable commodity as individual transferable quotas.

In some fisheries, the crew's contribution and its relevance for quota allocation has been a pressing political issue. Since fishing quotas are often allocated with reference to 'fishing history,' fishers, boat owners, and managers debate on what exactly makes fishing history, focusing on the relative importance of the vessel itself and its technology (favoring the owners of capital) and the crew (favoring labor power, in particular that of the skipper). A related contested issue involves the practical and theoretical merits of effort quotas (number of fishing trips) vis-à-vis catch quotas (size of catch).

The other main approach to fisheries management, comanagement (Jentoft, 1989), emphasizes democratic decision making and the importance of practical knowledge. A number of anthropological studies have shown that in many fishing societies people have developed indigenous means of regulating access to fishing grounds. In some cases, local groups of users successfully control the reproduction of renewable resources without external intervention, effectively comanaging local resources. In some parts of the world, especially Asia and the Pacific, comanagement has a long tradition (Ruddle and Johannes, 1985). Recently, such examples have attracted much attention among both researchers and managers, informed by renewed interest in 'indigenous' or 'traditional' ecological knowledge on the international scene (Dyer and McGoodwin, 1994) as well as growing doubts about the modernist concept of 'resource management,' with its assumptions of human mastery, control, and predictability.

Some of the growing body of works in this vein draws upon the 'institutional' scholarship of Elinor Ostrom. Emphasizing the context of scarce natural resources, including fisheries, Ostrom (2005) presents a framework for discussing the development and use of collective action with respect to environmental problems and common-pool resources, an alternative to both the governance of the nation state and the neoliberal solution of private property and the market. Drawing upon the 'new institutionalism' developed by Douglas North and some others, she underlines the impact and interrelations of social institutions (what anthropologists and sociologists would be likely to refer to as cultural or social context), comparing cases and contexts in order to generalize about the 'building blocks' of institutions.

The oceans have often been presented as a virtual showcase for radical experimental schemes in the terrestrial domain, for fleshing out central issues relating to 'tragedies' of the commons and the inevitability of privatization and neoliberal politics. For many economists, in particular, the fisheries have provided illuminating demonstrations of the need for 'final' market-based solutions to problems of access, sustainability, and governance, much like the solutions of state socialism decades earlier. For others, however, the neoliberalization of fishing stocks has paved the way for virtual economies and, eventually, the current global financial crisis. Several anthropologists and sociologists have critically examined particular management schemes emphasizing contrasting promises and broad community implications (Pinkerton and Edward, 2009).

Maritime Anthropology Coming of Age

Traditionally, anthropologists have focused on isolated communities. Modern anthropology, however, provides useful perspectives on cultural flows and the link between micro- and macrolevels. Recently, anthropological students of fishing societies have increasingly moved from the narrow context of face-to-face encounters and local communities to the nation state and beyond. Thus, several anthropological studies have drawn attention to the ways in which local and professional identities are constructed within larger contexts. Maritime

anthropology developed in the 1970s onward, along with anthropology at home, applied anthropology, and a series of other developments that redefined the sites, methods, politics, and subject matter of anthropological research.

Early on, maritime anthropology was heavily focused on the community at sea, navigation and wayfinding, fishing skills, competition for space, crews, and fleets. Later on the discussion broadened to include fishing communities, fish processing and marketing, property rights, and resource management. In the process, anthropologists carved an important professional niche for themselves in administration, development, and governance. Anthropological analyses and ethnographic insights proved to be quite useful for charting alternative regimes of resource use, for mitigating change, and for settling disputes relating to rights and access.

To the extent that Helmreich's (2009) work on the 'alien' ocean belongs to maritime anthropology, it takes a radical course back to the sea, into the depths of the ocean and the microworlds of cellular life. On the one hand, he explains, the ocean has been domesticated through immense human effort, brought into the human domain, charted, and analyzed with respect to chemistry, food webs, life forms, etc.; an interesting recent development on this score is the addition of the ocean floor, more than half of the globe's surface, to the area covered by Google Earth – an achievement underlining the conquest of the last cartographic frontier on the globe, allowing Internet explorers wherever they are based to virtually navigate the ocean bed. But on the other hand, the ocean remains a wild domain, saturated with life at the extremes in terms of heat, pressure, fleeting boundaries, and genomic configuration, full of strange species and alien genes, traveling between microbial lineages.

In recent years, the notion of the tree of life, a central notion for Darwin, Linnaeus, and much of biological thought since their time, has been seriously challenged by a strange mix of scholars. For one thing, it has been reasoned, the tree of life might turn out to be a net or a rhizome, with endless reconnections rather than treelike bifurcation. Also, this makes the oceans centrally relevant for biological theorizing, and the fleeting nature of biological processes in the aquatic domain may facilitate lateral gene transfer between organisms and species. 'Oceans,' Helmreich (2009: p. 280) suggests, 'are good to think with about life.' While it is possible that theoretical challenges to the tree model and the empirical evidence available only minimally blur the main picture, simply shaking the tree a bit, they raise fundamental questions as to what should count as relatedness. Maritime anthropology has come of age.

Five Factor Model of Personality, Assessment of

Michael J Boudreaux and Daniel J Ozer, University of California Riverside, Riverside, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Five Factor Model (FFM) is a hierarchical taxonomy of personality traits. At the superordinate level are five factors labeled Extraversion, Agreeableness, Conscientiousness, Emotional Stability (vs Neuroticism), and Intellect (or Openness). Below this level are several more specific personality traits that are summarized by these five higher-order dimensions. In this article, we briefly describe the lexical and questionnaire approaches that led to the development of the FFM, and review measures that derive from these two traditions, measuring both higher- and lower-order traits. In addition, we discuss abbreviated instruments, measures that assess variants of the FFM, an open source personality item pool, and a structured interview. Future research will improve upon FFM assessment by examining the five factor structure across languages and developmental periods, and detailing the structure of personality traits at lower levels of the trait hierarchy.

The Five Factor Model (FFM) is a hierarchical taxonomy of personality traits organized around five broad dimensions. While the lower levels of this taxonomy are only partially explored, the highest order level is composed of the superordinate factors labeled Extraversion, Agreeableness, Conscientiousness, Emotional Stability (vs Neuroticism), and Intellect (or Openness). Given the comprehensiveness of the FFM, one could understand any assessment of personality traits as an assessment of at least a portion of the FFM. For example, the Woodworth Personal Data Sheet, published in 1920, perhaps the first modern standardized self-report measure of personality, is an assessment of Neuroticism. However, our focus here is on more contemporary measures of personality traits that explicitly embrace or are close variants of the FFM.

Evidence supporting the FFM is necessarily linked to assessment efforts. The model arose out of the assessment tradition (see Wiggins, 1973, for a description of that tradition just as the FFM was beginning to emerge), and measures of the five factors were developed to improve, elaborate, supplant, or shorten prior trait measures. The consensus that emerged among personality trait assessors, that the FFM might indeed possess substantial generality, arose from two largely separate but converging research programs: the lexical and questionnaire approaches. The goal of the lexical approach was to identify the structure of self- and observer-rated trait descriptive adjectives, whereas the questionnaire approach sought to identify the common trait dimensions underlying extant multiscale personality inventories.

The term 'Five Factor Model' derives from the questionnaire tradition and is exemplified by the work of Paul Costa and Robert McCrae. Those working in the lexical tradition, including Warren Norman and Lewis Goldberg, have preferred the label 'Big Five.' One superficial difference between these traditions is in the naming of the fourth factor, 'Emotional Stability' (Big Five) or 'Neuroticism' (FFM). A more telling difference is in the conceptualization of the fifth factor as 'Intellect' (Big Five) or the broader 'Openness to Experience' (FFM). There is some movement toward a preference for the shorter label of 'Openness,' which suggests not only intellectual but also imaginative and affective components as well.

Below, we describe various English language measures of the five factors that evolved out of these two traditions, as well as efforts to create abbreviated Big Five/FFM measures. While there has been considerable consensus surrounding the five factors, there are close variants of six- and seven-factor measures that merit attention. Finally, we discuss an open source personality item pool, a structured interview for an FFM assessment, and studies that have examined the comparative validity of Big Five/FFM measures.

Goldberg and the Lexical Approach

The lexical hypothesis asserts that the most salient and socially relevant ways in which people differ from one another will eventually become encoded as words. Allport and Odbert's catalog of English language trait descriptive terms, published in 1936, provided a starting point for studying the structure of personality trait adjectives. In subsequent years, various investigators examined the factor structure of these terms in both self- and observer reports. As early as 1963, Warren Norman suggested that the reappearance of the same factors across different studies and samples suggested that five factors might provide an adequate taxonomy of personality traits, though this solution was not named the 'Big Five' until 1981, by Lewis Goldberg.

In the early 1980s, Goldberg initiated a series of studies designed to verify the five-factor structure. He returned to the lexicon of personality and constructed an inventory of 1710 trait descriptive adjectives. He replicated the Big Five factor structure across a variety of samples and factor analytic methods, and subsequently developed several abbreviated marker scales for the Big Five. In one of these (Goldberg, 1990; Study 2), he reduced the terms to 479, grouped into 133 clusters. Then, in study 3, he removed the least homogenous items from each cluster (i.e., those with the lowest item-total correlations), as well as single-item categories, resulting in a set of 100 clusters based on 339 trait adjectives. The 100 clusters and adjectives defining each cluster are available in Goldberg (1990; Table 3).

The 100 synonym clusters have several merits. Most notable is the balance between bandwidth and fidelity. The clusters

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25061-7

sample a broad range of personality characteristics, and each provides specific information that can be used for predictive purposes. However, the use of 100 synonym clusters is still time-consuming, so Goldberg (1992) developed two shorter measures: 50 bipolar rating scales (e.g., timid vs bold, rude vs polite, angry vs calm) and 100 unipolar markers (e.g., energetic, cooperative, relaxed). The rationale for using paired terms is that they can help clarify the ambiguity of some adjectives; however, Goldberg (1992) found that they are less robust across samples than factor markers presented in unipolar format. The bipolar rating scales are now less often used in research, but have been used in educational settings to demonstrate the nature of the Big Five (see Goldberg, 1992; Table 1).

Goldberg's (1992) 100 unipolar markers is an efficient and widely used measure of the Big Five. It contains 20 items per factor, with 10 items representing each pole of each factor (with the exception of Emotional Stability, which has 6 positive and 14 negative terms). From an initial pool of 566 terms, items were selected with high loadings on targeted factors and low loadings on other factors. Then, those items that maximized internal consistency and had a replicable factor structure were selected into the final list. Goldberg showed each of the five 20-item scales to be highly reliable (alpha coefficients above 0.80) and to converge with larger and more representative sets of trait adjectives, as well as with other inventories. The 100 unipolar markers are available in Goldberg (1992; Appendix A), and a 40-item, abbreviated version, the Big Five Mini-Markers, is available in Saucier (1994; Appendix). More recently, Saucier (2002) developed three sets of marker scales designed to reduce the interscale correlations often observed within Big Five measures, called the Ortho-Markers (Ortho-40), Modular Markers, and Mini-Modular Markers-40 (3M40).

Costa and McCrae and the Questionnaire Tradition

Numerous structured questionnaires to assess personality have been developed, with highly varied content and scales. Among these instruments was the NEO, developed by Paul Costa and Robert McCrae in 1980, which measured the three domains of Neuroticism, Extraversion, and Openness to Experience, and included 18 facet scales (6 per domain). Observing the findings reported by studies of the lexical structure noted above, they added (in 1985) scales to assess Agreeableness and Conscientious, and later developed (in 1992) facet scales to assess these domains. In a series of studies, Costa and McCrae found that the scales of some of the most widely known and frequently used personality measures could be placed within a five-factor framework. To be clear, their claim was not that all inventories measured all five factors (this was clearly not the case), but rather that inventory scales were largely related to the five (or a subset of the five); and scales that were outside the five-factor space were largely idiosyncratic to each inventory.

The Revised NEO Personality Inventory (NEO-PI-R; Costa and McCrae, 1992) is a 240-item questionnaire designed to measure the five major personality trait domains. Within each domain are six facet scales, with eight items per facet. The items are simple sentences that describe behaviors, preferences, and attitudes, and are responded to on a 5-point, Likert-type scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). The NEO-PI-R comes in two forms: Form S, for self-reports, and Form R, for observer ratings. Form R contains the same items as Form S, but is written in the third person. A more recent version of the NEO (NEO-PI-3, McCrae and Costa, 2010) was made to be applicable to a wider range of individuals, including school-aged children and respondents with lower levels of education. The NEO-PI-3 is thus appropriate for individuals who are 12 years of age or older.

The NEO-PI-R enjoys more than 30 years of research to support its reliability and validity. The scales are internally consistent, with alpha reliabilities for the domain scales in the range of 0.86–0.92 ($Mdn. = 0.89$), and for the facet scales in the range of 0.56–0.81 ($Mdn. = 0.76$). Scores show long-term stability, with retest values for the domain scales ranging 0.63–0.83 over 3–6 years. Six-year retest coefficients in spouse ratings, using Form R, are similar to those found in self-reports. The scales have also shown evidence of convergent and discriminant validity across instruments and observers. The NEO-PI-R has a clear internal structure, though some of the facet scales have large secondary loadings (i.e., >0.40) which contribute to modest correlations among the five NEO-PI-R domain scores. To obtain truly independent domain scores, factor score weights can be applied to each of the 30 facets (provided in the NEO-PI-R professional manual).

The Revised NEO Five-Factor Inventory (NEO-FFI-R; McCrae and Costa, 2004) is an abbreviated version of the NEO-PI-R. It consists of 60 items to measure the five global dimensions of the FFM, with 12 items per scale. In the original version of the instrument, items were selected based on their correlations with factor scores from the NEO-PI. The revised version replaced 14 of the original items, thus improving its factor structure, reliability, and validity. In an even more recent version, the NEO Five-Factor Inventory-3 (NEO-FFI-3; McCrae and Costa, 2010), one additional item was replaced. All items correspond with the NEO-PI-3. McCrae and Costa (2007) reported excellent psychometric characteristics of the NEO-FFI-3 in adolescent, adult, and middle-school samples.

McCrae and Costa (2007) also developed a brief measure of all 30 facet scales, corresponding to the first 120 items of the NEO-PI-3, the NEO-PI-3 First Half (NEO-PI-3FH). For those who desire a differentiated yet brief measure of the FFM, the NEO-PI-3FH provides a flexible alternative to both global and longer multitrait inventories.

The NEO Inventories have been used extensively in research and applied contexts as diverse as counseling and clinical psychology, behavioral medicine, industrial-organizational psychology, and educational psychology (Costa and McCrae, 1992), and are commercially available through their publisher, Personality Assessment Resources.

Brief Measures of the Big Five

As personality assessors increasingly regarded the five superordinate factors as an adequate summary view of personality traits, there arose an interest to include measures of these traits in various research contexts – contexts where the inclusion of a number of other measures led to a desire for a brief measure

of the Big Five. These short measures are now widely used in a number of research settings.

Big Five Inventory – 44-Item Version

The Big Five Inventory (BFI; John et al., 1991) is a brief, 44-item self-report inventory designed to measure the Big Five personality trait dimensions. The items are in the form of short phrases, written in the third person, and based on prototypical trait markers of the Big Five with elaborative or clarifying information added (e.g., "is original, comes up with new ideas," "is relaxed, handles stress well"). Each statement uses the stem, "I see myself as someone who …" Respondents indicate the extent to which they agree or disagree with each statement on a 5-point, Likert-type scale ranging from 1 (*disagree strongly*) to 5 (*agree strongly*).

The BFI scales include 8 to 10 items, and have very good psychometric properties: The scales are highly reliable (alpha coefficients range from 0.75 to 0.90, with an average above 0.80), stable over time (3-month retest coefficients range from 0.80 to 0.90, with a mean of 0.85), and possess convergent and discriminant validity with respect to other Big Five instruments (John et al., 2008). The BFI is widely used, and is reprinted in John et al. (2008; see Appendix 4.1).

Big Five Inventory – 10-Item Version

The Big Five Inventory-10 (BFI-10; Rammstedt and John, 2007) is an abbreviated version of the BFI-44. It consists of two items per scale, representing both the high and low poles of each factor. The response format is identical to the full BFI, although the instructions have been shortened. Items were selected based on their item-total correlations with the full BFI scales, as well as their factor loadings in analyses of all 44 items. Given the brevity of this measure, it holds up remarkably well across US and German samples: The two-item scales have an average correlation of 0.83 with the full scales, are stable over 6–8 weeks (average retest stability coefficient is 0.75), and have an average self-peer convergent validity correlation of 0.44. The BFI-10 scales possess substantial convergent and discriminant validity with the domain and facet scales of the NEO-PI-R, and the items show a clear five-factor structure. The BFI-10 takes about 1 min to complete. The items and instructions are provided in Rammstedt and John (2007; see Appendix A).

Ten-Item Personality Inventory

The Ten-Item Personality Inventory (TIPI; Gosling et al., 2003) is another short measure of the Big Five. Each item consists of paired descriptors (e.g., extraverted, enthusiastic) that use the common stem, "I see myself as:" Respondents indicate the extent to which they agree or disagree with each item on a 7-point, Likert-type scale ranging from 1 (*disagree strongly*) to 7 (*agree strongly*). In a large student sample, the psychometric properties of the TIPI reached satisfactory levels across three criteria: Scores converged with widely used Big Five measures, evinced substantial 60 week test–retest correlations (mean $r = 0.72$), and exhibited patterns of correlations with a broad range of other constructs that were comparable in size to those exhibited by the BFI in the same sample. The TIPI takes about 1 min to complete, and is provided in Gosling et al. (2003; see Appendix A).

Alternative Representations of Trait Structure

The questionnaires discussed to this point are widely understood to be different measures of the same five broad traits. The measures discussed below each embrace several features of the Big Five/FFM framework, while at the same time introduce important variations.

Abridged Big Five Dimensional Circumplex

The Abridged Big Five Dimensional Circumplex (AB5C; Hofstee et al., 1992) represents an integration of Big Five and Circumplex approaches to trait structure. The model recognizes that trait descriptors rarely show simple structure, but tend to show cross-loadings on two or more factors. It 'abridges' a full five-dimensional model, where each trait would load on all five factors, to a two-dimensional model, where each trait loads on two factors. Consisting of 10 two-dimensional circumplexes, with two of the five factors serving as the axes of each circle, the AB5C model has 45 facet scales (based on 540 trait terms) representing 'blends' of the two underlying factors (e.g., *sociable* (I+II+) corresponds to high Extraversion and high Agreeableness, and *dominant* (I+II−) corresponds to high Extraversion and low Agreeableness).

Big Seven Factor Model

The Big Seven Factor Model, and its associated measure, the Inventory of Personal Characteristics (IPC-7; Tellegen et al., 1991), specify seven higher-order factors: Positive Valence, Negative Valence, Positive Emotionality, Negative Emotionality, Conscientiousness, Agreeableness, and Conventionality. This model departs from the traditional Big Five in two important ways: First, by including in its item pool evaluative and state descriptors of personality, two primary dimensions of self-evaluation, Positive Valence (e.g., excellent, special, impressive) and Negative Valence (e.g., evil, wicked, awful), emerge in factor analyses in addition to the Big Five. Second, the factors labeled Positive Emotionality (Extraversion) and Negative Emotionality (Neuroticism) emphasize the emotional aspects of their Big Five counterparts, and Openness is reinterpreted as (low) Conventionality.

Waller (1999) reviewed Big Five and Big Seven models, and described the psychometric properties of the IPC-7. Benet and Waller (1995) demonstrated the cross-cultural generalizability of the IPC-7 in a Spanish sample using an abbreviated 70-item version. American and Spanish versions of the abbreviated IPC-7 are available in Benet and Waller (1995; Appendix).

HEXACO Personality Inventory – Revised

The Revised HEXACO Personality Inventory (HEXACO-PI-R; Lee and Ashton, 2004) is a 200-item questionnaire designed to measure six factors found in lexical studies of personality trait structure: Honesty-Humility (H), Emotionality (E),

Extraversion (X), Agreeableness (A), Conscientiousness (C), and Openness to Experience (O). The HEXACO factors are alternative rotations of the Big Five, and are defined by 24 facets (four per factor) within the HEXACO-PI-R. The major difference between the models is the separate dimension of Honesty-Humility within the HEXACO model, defined by sincerity, fairness, lack of greed, and modesty. Additionally, Emotionality (i.e., Emotional Stability) and Agreeableness (as well as Extraversion to a slight degree) have been reinterpreted. The HEXACO-PI-R (100- and 60-item versions) and a list of references are available on the HEXACO web site (http://hexaco.org).

Hogan Personality Inventory

The Hogan Personality Inventory (HPI; Hogan and Hogan, 1995) was designed to assess the FFM from the perspective of socioanalytic theory. According to socioanalytic theory, the FFM represents personality from the view of the observer in terms of a person's ability to 'get along' with other group members and to 'get ahead' to earn social status. The HPI assesses individual differences in a person's ability to attain these goals. It contains seven primary scales called, along with their FFM counterpart, Adjustment (Emotional Stability), Ambition and Sociability (Extraversion), Likeability (Agreeableness), Prudence (Conscientiousness), and Intellectance and School Success (Openness).

The HPI consists of 206 true-false items, grouped into 41 'homogenous item clusters' that define the seven primary scales. Hogan and Hogan (1995) reported the scales to be internally consistent (alpha reliabilities for the primary scales range from 0.71 to 0.86), to converge with other established Big Five measures, and to predict a variety of job performance criteria. The HPI has been used primarily in occupational settings, and is commercially available through Hogan Assessment Systems.

Revised Interpersonal Adjective Scales: Big Five

The Revised Interpersonal Adjective Scales: Big Five (IASR-B5; Trapnell and Wiggins, 1990) is an extension of the Revised Interpersonal Adjective Scales, a measure of the interpersonal circumplex. In addition to the interpersonal dimensions of Dominance (or Agency) and Nurturance (or Communion), the IASR-B5 includes marker scales for Neuroticism, Conscientiousness, and Openness to Experience. Although Dominance and Nurturance generally correspond to Extraversion and Agreeableness, the latter two dimensions are broader in content to include non-interpersonal aspects of personality.

The IASR-B5 consists of 124 adjectives rated on an 8-point, Likert-type scale ranging from 1 (*extremely inaccurate*) to 8 (*extremely accurate*). The first 64 items measure the Dominance and Nurturance dimensions of the interpersonal circle, and can be used to score the eight octants of the Interpersonal Adjective Scales. The remaining 60 items measure Neuroticism, Conscientiousness, and Openness to Experience (i.e., 20 items per factor, with 10 items marking the positive and 10 items marking the negative poles). Trapnell and Wiggins (1990) reported the IASR-B5 to have a clear internal structure at the item level, and discriminant and convergent validity when compared with the NEO and Hogan personality inventories.

Measures Derived from the International Personality Item Pool

The International Personality Item Pool (IPIP; Goldberg, 1999) is a repository of over 2000 personality items that have been used to develop a number of personality inventories, including measures of the FFM. Freely available in the public domain (http://ipip.ori.org), many of these measures serve as proxies for constructs measured by commercially available inventories, such as the NEO-PI-R and HPI, as well as nonproprietary instruments, such as the HEXACO-PI, the AB5C, and 100 unipolar markers. Tables comparing the psychometric characteristics of the original scales with the IPIP proxies can be found on the IPIP web site. As Goldberg et al. (2006) noted, alpha reliabilities of these scales generally match or exceed those of the original scales, and the IPIP scales correlate highly with their parent scales.

A noteworthy measure derived from the IPIP item pool is the Big Five Aspect Scales (BFAS; DeYoung et al., 2007), a 100-item inventory designed to assess two distinct (but correlated) 'aspects' of each factor (i.e., trait variables that occupy an intermediate level of personality structure between facets and domains). Item selection was based on correlating all of the IPIP items with scores derived from factor analyses of all 75 NEO-PI-R and AB5C-IPIP (Goldberg, 1999) facet scales. Then, in an independent sample, the 20 items showing the clearest two-factor solution within each domain were selected. The ten 10-item aspect scales demonstrated good psychometric characteristics, and were associated with factors derived from studies in behavioral genetics.

Structured Interview

Self-reports are the predominant source of personality data. However, alternative modes of assessment are sometimes desired. Although several observer rating forms are available for FFM measures, the instruments are largely the same as those used in the self-report versions with minor changes in wording and instructions to reflect the stance of the observer. One novel procedure for assessing the five factors utilizes a structured interview approach using a standard set of questions and scoring procedure. Mental health practitioners often prefer interview methods because they allow for open-ended, follow-up questions and an opportunity to observe the respondent's behavior during an assessment.

The Structured Interview for the Five-Factor Model of Personality (SIFFM; Trull and Widiger, 1997) is a 120-item semistructured interview that assesses both adaptive and maladaptive aspects of the FFM. It assesses the five higher-order dimensions (with 24 items per dimension) and 30 lower-order facet traits (with 4 items per facet), corresponding to the NEO-PI-R. The SIFFM places relatively greater emphasis on potentially maladaptive aspects of personality, and was explicitly designed to be used in clinical settings. The SIFFM items (i.e., interview questions) are scored as either 0 (*absent*), 1 (*present and does not result in significant dysfunction*), or 2

(*present and may result in significant dysfunction*). Follow-up questions may or may not be asked depending on the response to the initial question. The SIFFM takes about 1 h to administer.

In samples of undergraduates and outpatients receiving treatment at a community clinic, Trull et al. (1998) showed scores on the SIFFM to be internally consistent, stable across 2 weeks, and to converge with scores on the NEO-PI-R domain and facet scales and peer-ratings on the NEO-FFI. Trull et al. also demonstrated incremental validity of the SIFFM over the NEO-PI-R in predicting 10 of 13 personality disorders. Given its relative emphasis on maladaptive aspects of traits associated with the FFM, the SIFFM is primarily used by clinical researchers and practitioners to assess personality and personality dysfunction. The SIFFM is commercially available through its publisher, Personality Assessment Resources.

Comparative Validity of FFM Personality Inventories

Relatively few studies have compared the psychometric characteristics of FFM personality inventories, but some studies are beginning to appear. John and Soto (2007) compared the reliability and validity of the NEO-FFI, the BFI, and Saucier's (1994) 40-item version of Goldberg's (1992) 100 Trait Descriptive Adjectives (TDA). All three instruments showed relatively similar internal consistency coefficients, though some differences in convergent validity were noted for the NEO Extraversion and Openness scales. Profiles of the Big Five domains showed differences in terms of how the three measures define each factor with respect to the NEO-PI-R facet scales. As a result, patterns of intercorrelations vary somewhat across instruments, although the average discriminant within-instrument correlation is quite low, with an absolute value of 0.19 overall.

Grucza and Goldberg (2007) compared the validity of 11 personality inventories in predicting three criteria: frequencies of self-reported behavioral acts, informant reports, and clinical indicators. Among the instruments they reviewed, five were designed to assess the FFM – the NEO-PI-R, HPI, HEXACO-PI, TDA, and the IPIP-AB5C. Across the three criteria, the average multiple correlation coefficient fell between a narrow range of 0.42 (for the TDA) and 0.45 (for the NEO-PI-R), suggesting little difference in overall predictability for the instruments, though there were important differences for predicting particular criteria. Similarly, Saucier (2002) reported no overall predictive differences when comparing questionnaire measures (NEO-PI-R, NEO-FFI, BFI) and a variety of adjective-based marker scales (Mini-Markers, Ortho-40, Modular Markers, 3M40). Other studies have shown that narrower trait measures, such as the facet scales included in some of these instruments, can improve the prediction of behavior above and beyond the global domains (e.g., Paunonen and Ashton, 2001).

Conclusion

As reviewed above, numerous English-language measures of the five factors are available, varying in length and specificity. In addition, Big Five/FFM adjective- and phrase-based measures have been developed within other cultures and languages, several of which are reviewed in De Raad and Perugini (2002). Furthermore, measures designed to assess the Big Five/FFM in children have been developed. The adequacy of the five-factor framework to account for personality trait differences across languages and developmental periods remains to be fully explored, as does a taxonomy of trait structure that fully describes more specific personality traits. Research that extends the limits and explores the details of this hierarchical taxonomy will inevitably lead to new and presumably improved personality measures.

Abstract

In a hierarchical model of personality trait structure, a facet is defined as a narrow constituent trait that is subsumed under a broad factor. Although there are debates about the number and nature of these facets, they should not diminish the usefulness of such traits in predicting and explaining behavior. Compared to the broad factors of personality, not only do facets provide greater predictive validity of outcome criteria, they are also more helpful in identifying the precise mechanisms involved in explaining psychological phenomena. A few examples on how analyzing personality data at the facet level can yield novel and important findings are presented.

Personality psychologists have long espoused a hierarchical view of personality structure in which trait variables are arranged into several levels representing varying breadth of sampled behavior domains. Eysenck (1947) was probably the first theorist to formalize such a structure to personality, as shown in **Figure 1**. The lowest level of the hierarchy is represented by behavioral responses enacted in specific instances. Regular occurrence of a behavioral response across situations and time combines to form a habitual response, which represents the next level up in the hierarchy. Several habitual response propensities constitute a personality facet or trait at the third level. Finally, the top of the personality hierarchy represents several correlated personality facets that are connected to form the broad factors or dimensions of personality (Goldberg, 1993; Paunonen and Hong, 2015).

On Factors and Facets

The five factor (or the Big Five) model of personality (see John et al., 2008, for a review; and the following articles: Five Factor Model of Personality, Assessment of; Big Five Factor Model, Theory and Structure; Five Factor Model of Personality, Universality of) specifies a set of exactly five broad personality factors at the apex of the hierarchy. These factors are thought to capture most of the essential human variation in characteristic patterns of thinking, feeling, and behaving. The factors are commonly referred to as neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness. Each of these factors is presumed to subsume several lower-level personality facets or traits. Because facets are seen as occupying a conceptual space between broad factors and specific patterns of behavior, they are regarded as the basic building blocks of personality. Cattell (1946) called them *primary traits* as they represent the most basic characterization of a consistent pattern of thought, affect, and behavior. In contrast to the broad factors, the facets are conceived to be narrower in definition and thus to correspond to more circumscribed domains of behavior.

The personality trait hierarchy serves a crucial function as a taxonomy of stable individual differences characteristics. In biology, a taxonomy maps out the broad classification of living

Figure 1 A hierarchical model of personality organization (after Eysenck, 1947). From "Hierarchical organization of personality and prediction of behavior," by S.V. Paunonen, 1998, Journal of Personality and Social Psychology, 74, p. 539. Copyright 1998 by the American Psychological Association. Adapted with permission.

things based on shared characteristics (e.g., mammals), which then branches out with more differentiation that highlights differences between (but similarities within) subclasses (e.g., rodents, primates). In a similar vein, a personality taxonomy organizes traits with different levels of abstraction into a hierarchical fashion that allows for the description of distinct versus overlapping features among them. For instance, lower-level traits like achievement-striving and self-discipline are conceptually distinct, yet they share common features (e.g., propelling an individual to work hard in order to obtain mastery in task-related endeavors). Their commonality means they might both be classified under the higher-level dimension of Conscientiousness. Conversely, a trait like hostility, which shares hardly any commonality with the traits of achievement-striving or self-discipline, would probably not be subsumed under Conscientiousness and, instead, would define a different factor. The hierarchy thus enables researchers to get a sense of how individual traits might be clustered according to their functional similarities and differences.

An alternative view conceptualizes personality facets not as narrow traits that are subsumed under a broad Big Five factor but as varying blends of two Big Five factors (Hofstee et al., 1992). This view capitalizes on a circumplex model (i.e., a circular layout of traits) to organize the placement of personality factors and facets, and is best represented by the Abridged Big Five Circumplex scales from the International Personality Item Pool (AB5C-IPIP; Goldberg, 1999). Two Big Five factors (e.g., extraversion and agreeableness) can be paired to form a circumplex where they make up two orthogonal axes at 90° to each other. Ten such circumplexes with unique pairwise combinations of the five factors can thus be derived. Each of these circumplexes is then partitioned into 12 segments of 30 each and trait-descriptive items that fall within a segment and its polar opposite are thought to define a personality facet. Across the 10 circumplexes, each Big Five factor yields one facet that comprises items defining the factor itself and eight other facets that have secondary loadings with other Big Five factors.

The nature of the personality facet is fundamentally very different between the hierarchical and the circumplex models. In the former, a facet is considered to represent a rather narrow unidimensional psychological construct that is conceptually homogeneous and yet, at the same time, shares some common variance with other conceptually close facets to form a broad factor. Under the latter model, however, a facet is thought to intersperse between two broad factors of personality; hence it is conceptually heterogeneous as it takes in elements from the two different factors. In other words, facets in the hierarchical model represent relatively pure conceptual units of personality whereas facets in the circumplex model constitute derivatives from a process of amalgamation. It would seem that the way facets in the circumplex model are derived actually expands the conceptual space of the Big Five factors, giving detailed information on the intersections among the factors. However, the circumplex model facets do not help in elucidating the specific features within the Big Five factors themselves.

The hierarchical view takes precedence over the circumplex model in this article. Discussions in the following sections adhere to the view that personality facets should represent conceptually homogeneous entities that inform the specific aspects underlying the broad personality factors.

How Many and What Facets Are Important?

The definition of the five broad dimensions of personality as exemplified in the five factor model has reached wide consensus among researchers. The same cannot be said of the facet-level traits. One issue of contention has to do with what might be the optimal number of facets needed to measure the universe of individual differences adequately and comprehensively. Going by the range of the number of facet-level scales proposed by the developers of established personality inventories, it seems that nobody has the final say on this issue. The Revised NEO Personality Inventory (NEO-PI-R; Costa and McCrae, 1992) is probably considered by many to be the gold standard in measuring the five broad personality factors and their constituent facets. The NEO-PI-R specifies six facets to underlie each factor; hence a total of 30 facets make up the domain of personality in that model. But other assessment models exist. The AB5C-IPIP (Goldberg, 1999) measures a total 45 facet-level traits, nine for each of the five factors. A lexical analysis on trait-related words in natural language yielded 18 facets in at least one study (Saucier and Ostendorf, 1999). Several other inventories, though not developed originally to assess the five factor model, have been shown to yield (more or less) the same five broad factors via factor analysis, even with different numbers of facet-level traits. Cattell's Sixteen Personality Factor Questionnaire (16 PF; Cattell et al., 1993), as the name suggests, proposes 16 personality facets whereas Jackson's (1984) Personality Research Form-E has 20 facet-level trait scales. Simply put, there is hardly any consensus when it comes to the optimal number of lower-level personality facets in the five factor model.

A second debatable issue concerns the assignment of personality facets to the Big Five factors. Take the Extraversion factor as an example. The NEO-PI-R facets underlying Extraversion are represented by scales called Warmth, Gregariousness, Assertiveness, Activity, Excitement-Seeking, and Positive Emotions. Conversely, the 16 PF Extraversion facets include Warm–Reserved, Lively–Serious, Bold–Shy, Private–Forthright, and Self-Reliant–Group-Oriented. Although facets similar in content appear across the two inventories (e.g., NEO-PI-R Warmth and 16 PF Warm–Reserved), there are also facets that are unique to one inventory but not to the other. The NEO-PI-R does not have a facet that is conceptually close to the 16 PF Self-Reliant–Group-Oriented scale, for instance.

The glaring lack of agreement among theorists on the nature and number of facets that underlie each of the five broad dimensions of personality stems from differences in theoretical traditions and test construction strategies (e.g., theoretical-rational, empirical, and factor-analytic). This state of affairs for the facet-level traits is reminiscent of the debate two decades ago about the nature and number of the broad dimensions of personality (Block, 1995). Given the current consensus among personality psychologists on the five broad factors, it is expected that the exposition of personality facets should become clearer with future research. How a Big Five factor might be defined and what subcomponents such a factor

should entail are major questions waiting to be addressed. Some preliminary effort has been made to identify the important facets of Conscientiousness through joint factor analysis of Conscientiousness-related facet scales obtained from several established personality inventories (Roberts et al., 2005). The composition of facets underlying the other Big Five factors can be clarified using this strategy. Note that, as we will describe more fully later, not all researchers agree that every personality trait has a place under the umbrella of the Big Five factors (see Paunonen and Jackson, 2000).

Some Properties of Personality Facets

Are people accurate when judging the personality of others (*see* Person Perception, Accuracy of)? To what extent are personality traits heritable (*see* Personality Differences and Development: Genetic and Environmental Contributions)? Are personality traits stable or malleable across the life span (*see* Personality Development: Systems Theories)? These are but a small sample of questions that have intrigued personality psychologists for many years. Very often, researchers have relied on measuring the Big Five factors when addressing these questions. For example, with regard to the question about person perception, much research has been conducted at the level of the five factors. Hence, researchers would normally correlate a target's (i.e., the person being judged) self-ratings and an observer's ratings about the target on the Big Five factors. Similarly, if researchers are interested in the degree of genetic (vs environmental) contribution to personality characteristics, the typical unit of analysis has been at the factor level. However, there is nothing to prevent researchers from examining these same questions at the level of the facets or traits. The complexity of the research design and analysis would no doubt increase as they would have to deal with a larger number of variables (e.g., 30 facet scales, in the case of NEO-PI-R, vs just five factor scales). Still, the richness of information obtained may outweigh the cost of the additional complexity. In the sections below, several related observations associated with the facets of the five factor model are briefly reviewed.

Self-Observer Agreement

Numerous studies have shown that people can rate an acquaintance's personality characteristics with reasonably good accuracy (or agreement). For example, the self-observer agreement coefficients of the Big Five factors, as assessed by measures like the NEO-PI-R and the Big Five Inventory (BFI; see John et al., 2008), average around 0.40–0.50 (Costa and McCrae, 1992; John et al., 2008) among acquaintance ratings. For the facet scales, the self-observer agreement coefficients average around 0.35 for the NEO-PI-R (Costa and McCrae, 1992) and 0.45 for the BFI (Soto and John, 2009). The agreement coefficients for spouses are somewhat higher for both Big Five factors (mean = 0.60) and facets (mean = 0.50) than for acquaintances, as expected (Costa and McCrae, 1992).

The general picture suggests that observers' judgment accuracy drops a notch when rating the targets' personality facets compared to their personality factors. A possible explanation is that, compared to the factor scales, facet scales are usually less reliable due to a smaller item set. As a result, accuracy coefficients suffer because of less measurement reliability among the facets. Nonetheless, the self-observer agreement coefficients for the Big Five facets are still quite respectable, especially when the dyads are in intimate relationships. It seems that people can accurately rate each other on numerous specific domains of behavior, not just on a few global personality factors.

Heritability

A well-established finding in behavior genetic studies of personality is that approximately half of the variability in individual differences on the Big Five factors can be attributed to genetic factors and the other half mostly to nonshared environmental influences (Bouchard and Loehlin, 2001). If personality facets are considered to be narrow domains of behavior within the broad factors, then it should not be surprising that they show similar estimates of heritability. Indeed, research suggests that the facets have, on average, heritabilities hovering around 0.40 (Briley and Tucker-Drob, 2012; Jang et al., 1998). Jang et al. (1998) demonstrated that with the Big Five factors partialed out, the residual variance in facet scales still showed substantial heritability. This finding led those authors to conclude that personality facet scales are "measures of discrete constructs with a heritable and thus biological basis" (p. 1563).

A few studies have examined the genetic and environmental structure of facets using multivariate methods. The emerging picture is that a simple latent trait model cannot account for all the common variance among facets thought to define a single factor, at least for some of the Big Five factors (Briley and Tucker-Drob, 2012; Jang et al., 2002; Johnson and Krueger, 2004). These findings call into question whether higher-level factors like Agreeableness mediate most of the genetic (and environmental) influences on individual facets. Instead, the observation that a substantial amount of the genetic variability is specific to the facet-level traits suggests that they should not be ignored in favor of broader factor measures in personality research.

Personality Development

Personality stability or change over the life span can be quantified by two independent indices: (1) rank-order stability and (2) mean-level change. Rank-order stability refers to the stability of the relative positions of individuals on a personality characteristic over time whereas mean-level change refers to how a trait level, averaged across a sample of individuals, might change over time.

Personality facets in adults appear to exhibit strong rank-order stabilities over long periods of time. For instance, Terracciano et al. (2006) reported that the median stability of NEO-PI-R facets over an average of 10 years was 0.70 (range = 0.57–0.82), which was slightly lower than that of the NEO-PI-R factors (median = 0.81; range = 0.78–0.85). This finding indicates that people's relative standings on individual traits do not change much over long time intervals during adulthood.

The analysis of mean-level changes in personality facets has produced very interesting insights. In both cross-sectional and

longitudinal studies, there is evidence that facets belonging to the same factor can show divergent developmental trajectories (Soto and John, 2012; Soto et al., 2011). From age 20 to about 60, conscientiousness exhibited an upward age trend (i.e., older adults being more conscientious than younger adults; Soto et al., 2011), and this was supported by longitudinal data as well (Soto and John, 2012). Facet-level analysis indicated that this trajectory for broad conscientiousness was driven specifically by facets of industriousness and self-discipline but not orderliness. Orderliness did not change much as a function of age. It seems that the additional life responsibilities for older adults elicit greater levels of achievement-related traits compared to younger adults, but these life tasks do not modulate the level of orderliness across ages. Extraversion facets also showed divergent trajectories: assertiveness and social confidence increased whereas gregariousness decreased over time (Soto and John, 2012). This is in line with the hypothesis that the dominance component of extraversion increases due to the enlarged occupational and social role responsibilities older adults take on, whereas the gregariousness aspect decreases as older adults become more selective in terms of who they socialize with (Roberts et al., 2006). Together, these preliminary findings highlight the advances in knowledge when developmental trends are tracked at the facet level, and not just at the factor level.

Prediction of Outcome Criteria

An appealing feature of a hierarchical organization of personality variables is the flexibility afforded to use either the broad factors or the narrow facets (or both) in the prediction of outcome criteria. A broad personality factor provides bandwidth in prediction through its ability to predict across a variety of criteria, though the strength of those associations may be modest. Conversely, a narrow personality facet offers fidelity by ensuring strong prediction of a smaller number of specific criterion variables (Cronbach and Gleser, 1957). The vast majority of empirical research in psychology has relied on the Big Five factors as predictors of consequential outcomes, with great success in many cases. The use of narrow personality traits as predictors, unfortunately, has not enjoyed the widespread acceptance that it should. We believe that the potential for facets to increase predictive power and explanatory value of personality constructs is immense, and we outline our reasons in the following sections (Paunonen and Hong, 2015).

Specific Variance in Facets

As the basic building blocks of personality, each facet-level trait represents a consistent pattern of thinking, feeling, and behaving that is psychologically coherent (e.g., gregariousness, modesty, orderliness). Several facets thought to be subsumed under a single global factor are expected to correlate with one another. Still, most of these correlations are not close to perfect, suggesting that each facet retains some unique aspects not found in other related facets (i.e., nonredundancy).

In most personality inventories, a score on a broad factor measure is derived by aggregating separate scores on several facet-level scales. This can be done in two ways. The first is to take the sum or average across the constituent facet scores, each unit-weighted so that they contribute equally to the broad factor measure. By emphasizing the common core that represents the factor, the unique variance associated with each facet is diluted. The second method is to estimate the broader factor from its constituent facets via a common factor analytic model. In such a model, facets are considered to be indicators of an underlying factor construct, and their unique variances are regarded as error and thus discarded. The factor loadings form the weights by which the facets are aggregated to derive the factor's score. Doing so means that any nonrandom variance specific to a particular facet is thrown out in favor of the common factor variance underlying those facets. In other words, individuating information provided by each of the facets has been diluted or omitted when they are aggregated into a single broad factor via these two methods. It could very well be that the lost trait-specific variance that exists at the facet level is highly predictive of some criterion of interest.

It is not hard to imagine a hypothetical scenario where two lower-level facets that underlie a higher-level factor exhibit opposite associations with an external criterion. One facet shows a positive association with the criterion whereas the other shows a negative relation; the net effect is that the factor (aggregated from the facets) would yield no relation with the criterion (see O'Neill and Paunonen, 2013, for examples). The more common situation in empirical data is that a facet might predict a criterion, but its predictive capability is masked when it gets aggregated with other facets (which are not related to the criterion). It would be short-sighted if one were to conclude that no relation exists between the factor and the criterion, when even one specific aspect of that factor (i.e., a facet) shows predictive validity. Therefore, researchers should be cognizant about the possibility of losing criterion-valid but facet-specific variance when only broad personality factors are used for prediction.

Predictive Validity of the Facets

Some have argued that facet-specific variance is not generally useful for criterion prediction and that little statistical utility can be obtained in behavior prediction by using personality predictors other than the five broad factors (Ones and Viswesvaran, 1996). If that is true, then adding narrow facets of personality to the broad personality factors in a prediction context should not increase the predictive accuracy of outcome criteria. This question of whether facet-level personality variables are useful to the prediction of criteria relative to factor-level personality variables can be addressed empirically.

In a series of studies, Paunonen and colleagues have demonstrated that facets provide incremental validity beyond the factors in the prediction of a wide variety of behavior of some social importance, such as alcohol/tobacco consumption, grade-point average, and dating variety (Paunonen, 1998; Paunonen and Ashton, 2001). Take predicting grade-point average as an example in Paunonen and Ashton's (2001) study. The amount of criterion variance in grade-point average accounted for by the five NEO-PI-R factors combined was 11.1%. On the other hand, using five NEO-PI-R facets in the prediction equation, rationally selected by judges as traits likely to be related to grades, accounted for 15.3% of criterion

variance (Paunonen and Ashton, 2013). More important, personality facets afforded such predictive validity superiority over the personality factors across many criteria.

The predictive advantage of the facet-level traits over their factor-level counterparts has been demonstrated in the prediction of a wide array of other outcomes, including job performance (Vinchur et al., 1998), externalizing behavior (Miller et al., 2008), prejudice (Ekehammar and Akrami, 2007), and mortality (Turiano et al., 2012). Collectively, these studies point to the importance of personality facets, because the gain in predictive accuracy over the personality factors can be substantial.

Correspondence in Complexity of Predictor and Criterion

Ones and Viswesvaran (1996) have put forth an argument that optimal prediction occurs if there is a match in terms of the factorial complexity of the predictor and criterion variables. That is, if a criterion is a multidimensional construct (e.g., job performance), then accuracy in prediction would be best achieved by using a multidimensional predictor. Such a predictor might be a linear composite of several unidimensional variables derived through aggregation and then used as a single predictor in a standard correlational analysis. However, Paunonen (1998; Paunonen and Ashton, 2001) noted that there is no mathematical requirement that the predictor and criterion complexities must correspond to each other for successful prediction. Nunnally's (1978) advice with regard to maximizing prediction of the multidimensional criterion is worth reiterating here:

> As some will argue, the criterion usually is factorially complex and consequently can be predicted best by a factorially complex predictor test. Instead of building the factorial complexity into a particular test, it is far better to meet the factorial complexity by combining tests in a battery by multiple regression, in which case tests would be selected to measure the different factors that are thought to be important.
>
> p. 268

There is no inherent advantage in using a factorially complex predictor such as a broad personality dimension to predict a similar factorially complex criterion such as job performance. A more defensible strategy is to include a number of unidimensional facet-level traits in a multiple regression context to predict a criterion variable, be it factorially complex or not (Christiansen and Robie, 2011). Optimal prediction should occur when personality facets are judiciously selected based on theoretical reasoning or prior empirical evidence (O'Neill and Paunonen, 2013).

Contribution to Behavior Understanding

The advantage of facet-level assessment over factor-level assessments applies not just to behavior prediction but also to behavior understanding as well. When an association is found between a personality factor and a criterion, a logical next step is to examine if any of the facets that are supposedly subsumed under this factor might be driving this association. Engaging in such fine-grained analysis has the benefit of identifying specific 'active ingredients' – facets that are responsible for the behavior outcome. For example, Hong and Paunonen (2009) isolated the NEO-PI-R facet scale of Deliberation (a Conscientiousness facet) as a common and robust predictor of several health-risk behaviors. This suggested that a failure in careful deliberation (i.e., not thinking of the consequences of one's actions and acting hastily) can lead one to engage in activities that are potentially health-damaging. By the same token, it would also mean that the engagement in such risky behaviors has nothing to do with other Conscientiousness-related facets such as a sense of mastery (i.e., NEO-PI-R facet scale of Competence) or being methodical and organized (i.e., NEO-PI-R facet scale of Order). This sort of precise information would not only be very useful for theory development but also for guiding good psychological practices (e.g., designing intervention programs).

Facets beyond the Five Factor Model

The focus of this article has been on the facets associated with the five factor model and how they can be exploited for better prediction and explanation of behavior. But it is important to note in this context the existence of facet-level traits that have little variance in common with the Big Five factors, but are nonetheless important individual differences variables that have behavioral consequences. Paunonen and Jackson (2000), for example, identified 10 such traits, including manipulativeness, femininity, and egotism, thought to be not well represented within the Big Five space. Although these facets are omitted from the five factor model, the fact that they represent stable personality characteristics makes them no less important than the Big Five facets. Exclusion of those traits means risking the possibility that the predictability of certain criterion outcomes might be compromised (e.g., Hong and Paunonen, 2009).

Summary

The assertion that one should consider and employ narrow personality facets in predicting and explaining behavior is not a call to abandon the use of broad personality factors altogether. Without a doubt, using personality factors as predictors can yield informative findings especially when the area of inquiry is new. However, when a sizable literature has accrued with respect to factor–criterion associations, it would be timely and appropriate to apply more fine-grained analysis using personality facets. From this perspective, analysis of personality at the facet level supplements, rather than replaces, the data provided by the factors. In fact, it can offer a particularly rich and detailed picture into the psychological mechanisms responsible for crucial outcomes. The factors at the top of the personality hierarchy might be too broad to provide the specificity of information needed. At the other extreme, the specific responses at the bottom of the hierarchy can be overly narrow, and the large number of these responses can make prediction cumbersome and inefficient. Assessment at the level of the unitary personality facet or trait seems about right, yielding sufficient precise information for accurate behavior prediction and understanding.

Conclusion

Much is known about the Big Five factors – their nature, origins, and associations with other constructs. Advances in current knowledge on personality traits now demand exploiting the numerous facets that underlie those five factors. As maintained throughout this article, the advantages of examining personality facets for behavior prediction and explanation are numerous and their inclusion in research agendas should be routinely considered.

Five Factor Model of Personality, Personality Disorder

Cristina Crego and Thomas A Widiger, University of Kentucky, Lexington, KY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

It is evident that the conceptualization, diagnosis, and classification of personality disorder are shifting toward a dimensional trait model and, more specifically, the five-factor model (FFM) in particular. The purpose of this article is to provide an overview of the FFM of personality disorder. It will begin with a description of this dimensional model of normal and abnormal personality functioning, along with a brief overview of its empirical support. This will be followed by a discussion of its potential advantages, as well as a comparison with Section III of DSM-5 for emerging models and measures.

The diagnosis and classification of psychopathology is shifting to a dimensional model (Widiger and Gore, in press). The primary authors of the current, fifth edition of the American Psychiatric Association's (APA) Diagnostic and Statistical Manual of Mental Disorders (DSM-5; APA, 2013) stated that the primary goal of this latest edition was to begin this shift. "We have decided that one, if not the major, difference between DSM-IV and DSM-V will be the more prominent use of dimensional measures" (Regier et al., 2009: p. 649).

Most (if not all) mental disorders appear to be the result of an array of biological vulnerabilities and dispositions interacting in complex ways with a variety of environmental, psychosocial events that often exert their effects over a progressively developing period of time (Widiger and Gore, in press). The symptoms and pathologies of mental disorders are very responsive to a wide variety of neurobiological, interpersonal, cognitive, and other mediating and moderating variables that help to develop, shape, and form a particular individual's psychopathology profile. This complex etiological history is unlikely to be well described by single diagnostic categories that attempt to make distinctions at nonexistent discrete joints. Patients rarely meet diagnostic criteria for just one disorder; there is no clear boundary between the presence versus absence of any mental disorder; specific etiologies, pathologies, and treatments are not being discovered; and patients who meet the criteria for the same disorder are often different in very important ways from one another (Regier et al., 2009). As acknowledged in the introduction to DSM-5, "the once plausible goal of identifying homogeneous populations for treatment and research resulted in narrow diagnostic categories that did not capture clinical reality, symptom heterogeneity within disorders, and significant sharing of symptoms across multiple disorders" (APA, 2013: 12). It is further asserted that dimensional approaches will "supersede current categorical approaches in coming years" (p. 13).

The domain of psychopathology for which this shift is most readily suitable is the personality disorders (Widiger and Trull, 2007). The purpose of this article is to describe and discuss a particular dimensional trait model of personality disorder from the perspective of the five-factor model (FFM).

FFM of Personality

Most models of personality (and personality disorder) have been developed through the speculations and insights of prominent theorists. The development of the FFM was instead empirical; specifically, through studies of trait terms within existing languages. This lexical paradigm is guided by the hypothesis that what is of most importance, interest, or meaning will be encoded within the language. Language can be understood as a sedimentary deposit of people's observations over thousands of years of the respective language's development, usage, and transformation. The most important domains of personality are those with the greatest number of terms to describe and differentiate their various manifestations and nuances, and the structure of personality will be evident in the empirical relationship among these trait terms (Goldberg, 1993).

The initial lexical studies were conducted on the English language, and these investigations converged onto a five-factor structure (Goldberg, 1993), consisting of extraversion, agreeableness, conscientiousness, emotional instability, and openness (or unconventionality). Subsequent lexical studies have been conducted on the German, Dutch, Czech, Polish, Russian, Italian, Spanish, Hebrew, Hungarian, Turkish, Korean, Filipino, and other languages, and the findings have supported well the universal existence of the five domains, albeit replication is the strongest for the three domains that invariably appear first (i.e., extraversion, agreeableness, and conscientiousness; De Raad et al., 2010).

The universality of the FFM domains is not terribly surprising when one considers their content. The two relatively largest domains (extraversion and agreeableness) concern all manner of interpersonal relatedness. It is to be expected that the domains of personality functioning considered to be most important to people across all cultures and languages when describing themselves and others would concern how people relate to one another. The third domain of the FFM is conscientiousness (otherwise known as constraint). This domain concerns the control and regulation of behavior, and contrasts being disciplined, compulsive, dutiful, conscientious, deliberate, workaholic, and achievement-oriented, with being carefree, irresponsible, lax, impulsive, spontaneous, disinhibited,

negligent, and hedonistic. It is again perhaps self-evident that all cultures would find it important to describe the likelihood that a person will be responsible, conscientious, competent, and diligent as a mate, parent, friend, employee, or colleague. The fourth domain, emotional instability, is of considerable importance in the fields of clinical psychology and psychiatry, saturating most measures of personality disorder. It is again not surprising that most, and perhaps all, cultures consider the emotional stability (anxiousness, depressiveness, irritability, volatility, anger, and vulnerability) of its partners, children, friends, workers, laborers, and employees to be of considerable importance. The fifth domain, openness, intellect, or unconventionality, reflects a culture or society's interest in creativity, intellect, and imagination, contrasting being open-minded, unusual, odd, weird, creative, peculiar, and unconventional versus being closed-minded, practical, conventional, and rigid. After that, there is really very little that is left, if anything. It is in fact difficult to identify a trait term that lies outside of the five domains of extraversion (vs introversion), agreeableness (vs antagonism), conscientiousness (vs disinhibition), emotional instability, and unconventionality (vs conventionality).

There are both adaptive and maladaptive components for each of the 10 poles of the five FFM domains. The language is not proportional in the extent to which there are adaptive and maladaptive trait terms within each of the 10 poles. There are substantially more undesirable (and fewer desirable) trait terms for introversion, antagonism, disinhibition, emotional instability, and conventionality, than there are for extraversion, agreeableness, conscientiousness, emotional stability, and unconventionality (respectively). Nevertheless, there are undesirable trait terms for both poles of all five domains, including extraversion (e.g., flaunty, showy, and long-winded), agreeable (e.g., ingratiating and dependent), conscientious (e.g., leisureless, perfectionistic, workaholic, and stringent), unconventionality (e.g., strange, peculiar, and weird), and even emotional stability (e.g., emotionless, glib, and fearless). Table 1 provides illustrative traits within the normal range (largely adaptive) and the more abnormal extreme range for both poles of the six facets of agreeableness versus antagonism.

Since its original conceptualization through the lexical research, the FFM has amassed a considerable body of empirical support, including multivariate behavior genetics with respect to its structure (and even molecular genetic support for neuroticism), cortical functioning and structure, childhood antecedents, temporal stability across the life span, and cross-cultural validity, both through emic studies considering the structures indigenous to such languages and etic studies that address whether the FFM replicates well across major regions of the world, including North America, South America, Western Europe, Eastern Europe, Southern Europe, the Middle East, Africa, Oceania, South–Southeast Asia, and East Asia (Widiger et al., 2012). The FFM has also been shown across a remarkably vast empirical literature to be useful in predicting a substantial number of important life outcomes, both positive and negative, such as subjective well-being, social acceptance, relationship conflict, marital status, academic success, criminality, unemployment, physical health, mental health, job satisfaction, and mortality (Ozer and Benet-Martinez, 2006). The FFM is understandably the predominant dimensional model of general personality structure within psychology (John et al., 2008).

FFM and Personality Disorder

One of the strengths of the FFM is its robustness (John et al., 2008). Consistent with its comprehensiveness in the coverage of traits within the language, the FFM has been used effectively in many literature reviews as a basis for comparing, contrasting, and integrating diverse sets of personality scales and constructs (Widiger et al., 2012). The FFM is comparably robust in its coverage of abnormal as well as normal personality functioning. A substantial body of research now indicates that the FFM successfully accounts for the symptoms and traits of the DSM-IV (now DSM-5) personality disorders (Samuel and Widiger, 2008; Widiger et al., 2013b). Consider, for example, obsessive-compulsive personality disorder (OCPD). It is not difficult to understand that compulsivity, and much of the traits of OCPD, are maladaptive variants of FFM conscientiousness. The essential feature of OCPD is 'a preoccupation with orderliness, perfectionism, and mental and interpersonal control' (APA, 2013: 678), including within its diagnostic criteria such traits as perfectionism, preoccupation with order and organization, workaholism, and, quite explicitly, overconscientiousness. Similarly, FFM conscientiousness includes such facets as order, discipline, achievement-striving, and deliberation. It would seem apparent that maladaptive and/or extreme variants of order, discipline, achievement-striving, and deliberation would be the OCPD traits of perfectionism, preoccupation with order and organization, workaholism, and overconscientiousness.

Existing measures of the FFM can in fact be used to assess for the presence of a DSM-IV or DSM-5 personality disorder. A clinician or researcher can correlate an individual's scores on the 30 facets of the FFM with the FFM profile of a prototypic case of a respective personality disorder. This correlation can then serve as an index of the extent to which the individual's personality structure matches a respective DSM-5 personality

Table 1 Normal (adaptive) and abnormal (maladaptive) variants of facets of agreeableness

Facet	*Maladaptively low*	*Low*	*High*	*Maladaptively high*
Trust	Gullible	Trusting	Cautious, skeptical	Cynical, suspicious
Straightforwardness	Guileless	Honest, forthright	Savvy, cunning, shrewd	Deceptive, dishonest, manipulative
Altruism	Self-sacrificial, selfless	Giving, generous	Frugal, withholding	Greedy, self-centered, exploitative
Compliance	Yielding, subservient, meek	Cooperative, obedient, deferential	Critical, contrary	Combative, aggressive
Modesty	Self-effacing, self-denigrating	Humble, modest, unassuming	Confident, self-assured	Boastful, vain, pretentious, arrogant
Tender-mindedness	Overly soft-hearted	Empathic, sympathetic, gentle	Strong, tough	Callous, merciless, ruthless

disorder. Studies have consistently indicated that this correlation provides as a valid measure of a respective personality disorder, such as borderline, antisocial, or avoidant, as would be provided by the more traditional inventories for their assessment (Miller, 2012).

These quantitative prototype matching indices, however, have not worked as well for the assessment of the dependent, schizotypal, and OCPD (Miller, 2012). This probably reflects the fact that the traditional measures of the FFM lack adequate fidelity for the assessment of maladaptive variants of some of the FFM domains, particularly agreeableness, conscientiousness, and openness; and it is precisely these domains that are especially important for the assessment of the dependent, OCPD, and schizotypal personality disorders. However, researchers are now developing new measures of the FFM that are focused in particular on the maladaptive variants of its domains and facets (e.g., De Clercq et al., 2006). For example, there are self-report measures for eight of the 10 DSM-5 personality disorders from the perspective of the FFM, including (for instance) the dependent, obsessive-compulsive, and schizotypal, as well as the borderline, narcissistic, avoidant, histrionic, and antisocial (Widiger et al., 2012).

Clinicians and researchers can use these FFM personality disorder scales in two different ways. One approach, consistent with the more traditional conceptualization of a DSM-5 personality disorder, is to sum the scores for the scales for a respective syndrome to assess that particular personality disorder from the perspective of the FFM. For example, one can combine the 12 scales of the Five Factor Borderline Inventory (FFBI; Mullins-Sweatt et al., 2012) into one score to assess borderline personality disorder (BPD) from the perspective of the FFM. This approach is consistent with existing measures of BPD. An important distinction though between the FFBI and traditional measures of BPD is that the FFBI items and scales were coordinated conceptually and empirically with the FFM of general personality structure. Considering personality disorders from the perspective of the FFM will be useful in the development of a more integrative understanding of normal and abnormal personality (Clark, 2007; Widiger and Trull, 2007). To the extent that disorders of personality are understood as maladaptive variants of the FFM, one can bring to these personality disorders the extensive construct validity research concerning the genetics, childhood antecedents, course, universality, and positive and negative life outcomes identified for the FFM (Widiger et al., 2012).

Another approach to these instruments is to use only a subset of the scales. For example, a clinician or researcher might be interested in only assessing for maladaptive variants of agreeableness. This person might then use only the Gullibility, Selflessness, Subservience, and Self-Effacing scales from the Five-Factor Dependency Inventory. Alternatively, the clinician or researcher might wish to consider subscales from different personality disorders, such as all the various maladaptive variants of extraversion, including, for instance, the Dominance and Thrill Seeking scales from the Elemental Psychopathy Assessment, the Exhibitionism and Authoritativeness scales from the Five Factor Narcissism Inventory, and the Attention-Seeking, Social Butterfly, and Flirtatiousness scales from the Five-Factor Histrionic Inventory.

FFM Diagnosis of Personality Disorder

The purpose of the FFM of personality disorder is not simply to provide another means with which to diagnose the DSM-5 personality disorders. The purpose is, instead, to replace the diagnostic categories with a more valid and credible dimensional model of personality disorder classification. Widiger et al. (2013a) provide a four-step procedure for the diagnosis of a personality disorder from the perspective of the FFM (the fourth step, although, is optional).

The first step is to obtain an FFM description. There are a wide variety of alternative measures of the FFM that are readily available for this assessment, such as the NEO Personality Inventory-Revised, the Five-Factor Model Rating Form, and the International Personality Item Pool (Samuel, 2013). The second step is to identify problems in living and/or maladaptive traits that are associated with elevations on a respective facet of the FFM. The two outside columns of **Table 1** provide illustrative examples of the maladaptive variants of the FFM facets for agreeableness versus antagonism. As noted earlier, there are also now a number of alternative measures to assess for these maladaptive variants (e.g., De Clercq et al., 2006; Widiger et al., 2012).

The third step is to determine whether the impairments are at a clinically significant level warranting a diagnosis of a personality disorder. The diagnostic thresholds for most of the DSM-5 personality disorders were not based on any explicit or published rationale. The FFM of personality disorder, in contrast, proposes a uniform and consistent basis for determining when a disorder is present; more specifically, the level of impairment in social and occupational functioning as indicated in the global assessment of functioning scale (Widiger and Trull, 2007). A score of 71 or above on this scale indicates a normal range (e.g., problems are transient and expectable reactions to stressors); a score of 60 or below represents a clinically significant level of impairment (moderate difficulty in social or occupational functioning, such as having few friends or significant conflicts with coworkers).

The fourth step is the prototype matching described earlier, in which one correlates the FFM trait profile of a patient with the profile for a prototypic case of a respective personality disorder. This step is optional, provided for those who still wish to continue to use single diagnostic terms to describe a patient's personality profile. The FFM prototype matching provides a cross-walk between the FFM trait model and the DSM-5 syndromal approach. In fact, clinicians and researchers interested in studying diagnostic constructs that are outside of the existing nomenclature can use the FFM to provide a reasonably specific description of a clinical construct that is not currently recognized within the DSM-5 diagnostic manual, such as depressive personality disorder, vulnerable narcissism, alexithymia, or successful psychopathy (Mullins-Sweatt et al., 2010).

Advantages of an FFM of Personality Disorder

Shifting from the diagnostic categories of *DSM-5* to the dimensional traits of the FFM provides a number of

improvements and advantages over the existing nomenclature (Widiger et al., 2012). A few of these are discussed briefly in turn.

Individualized and Precise Description

One advantage of the FFM of personality disorder is simply a reflection of its dimensional format. Rather than force an individual into a category that fails to provide a fully accurate description, fails to capture important personality traits, and includes traits that the person does not have, the FFM allows the clinician to provide an individualized profile of precisely the traits that are present. This dimensional trait description would be considerably more precise and accurate than the existing DSM-5 categories, and, as a result, have obvious benefits for treatment, research, insurance, and other social, clinical decisions.

For example, a trait-specific description will be very helpful for treatment decisions. It is evident that treatment does not address or focus on the entire personality gestalt. Instead, clinicians treat, for instance, the affective instability, the behavioral dyscontrol, the despondence, or the self-mutilation of persons diagnosed with BPD, which are specifically identified within the FFBI (Mullins-Sweatt et al., 2012). Effective therapeutic change occurs with respect to these particular components of the disorder rather than with the entire, global construct, and it would then make sense that these specific facets of the syndrome be assessed individually.

The FFM conceptualization of each personality disorder enables researchers as well to disambiguate the DSM-5 diagnostic constructs and determine which particular component of the disorder best explains any particular finding. For example, rather than attribute a finding to the broad construct of schizotypal personality disorder, one can determine more precisely whether it reflects the social withdrawal, suspiciousness, or cognitive-perceptual aberrations. Lynam and Widiger (2007) demonstrated this point with respect to psychopathy, indicating how alternative theories for its core pathology (e.g., response modulation, lack of empathy, or fearlessness) reflect a differential emphasis on its different FFM components (e.g., low conscientiousness, the callousness of antagonism, or the fearlessness of low neuroticism, respectively).

Homogeneous Trait Constructs

The facet and domain constructs of the FFM are considerably more homogeneous than the DSM-5 diagnostic categories. The value of homogeneous diagnostic constructs has long been recognized within psychiatry but not well appreciated within the field of personality disorder. Two persons can meet the diagnostic criteria for the DSM-5 antisocial, borderline, schizoid, schizotypal, narcissistic, and avoidant personality disorders and yet in each case have only one diagnostic feature in common. This heterogeneity handicaps tremendously the effort to identity a specific etiology, pathology, or treatment for a respective personality disorder as there is tremendous variation within any particular group of patients sharing the same diagnosis.

The primary purpose of the APA diagnostic manual is to facilitate treatment planning (APA, 2013). However, it has been over 20 years since the APA has been developing practice guidelines for each of the disorders included within the DSM-5 and to date guidelines have been published for only one personality disorder: borderline. One possible reason for the absence of empirically based manualized treatment plans for personality disorders might be their complex heterogeneity. Given the substantial variability of defining features within each diagnostic category, it would be understandably difficult to develop a uniform treatment program for persons sharing the same personality disorder diagnosis.

The factor analytically based domains of the FFM might be better suited for treatment planning than the DSM-5 personality disorder diagnoses because they are considerably more distinct and homogeneous. Extraversion and agreeableness are concerned specifically with social, interpersonal dysfunction, an area of functioning that is relevant to relationship quality both outside and within the therapy office. Interpersonal models of therapy, marital-family therapy, and group therapy might be particularly suitable for these two domains. In contrast, neuroticism provides information with respect to mood, anxiety, and emotional dyscontrol, often targets for pharmacologic interventions, as well as cognitive, behavioral, and/or psychodynamic therapy. There are very clear pharmacologic implications for mood and anxiety dysregulation and emotional instability (e.g., anxiolytics, antidepressants, and/or mood stabilizers), but little to none for maladaptive antagonism or introversion, the interpersonal domains of the FFM. Maladaptively high openness implies cognitive-perceptual aberrations, and so would likely have pharmacologic implications (i.e., neuroleptics) that are quite different from those for neuroticism. The domain of conscientiousness, in contrast to agreeableness and extraversion, is the domain of most specific relevance to occupational dysfunction, or impairments concerning work and career. Maladaptively high levels involve workaholism, perfectionism, and compulsivity; low levels involve laxness, negligence, and irresponsibility. There might be specific pharmacologic treatment implications for low conscientiousness (e.g., methylphenidates) although, as yet, none for maladaptively high conscientiousness. Perhaps there never will be a pharmacotherapy for high conscientiousness, but the point is that the structure of the FFM could very well be more commensurate with more specific treatment implications than the existing diagnostic categories.

Inclusion of Normal, Adaptive Traits

An additional advantage of the FFM of personality disorder is the inclusion of normal, adaptive traits. The personality disorders are among the more stigmatizing labels within the diagnostic manual. They are relatively unique in concerning 'ego-syntonic' aspects of the self, or one's characteristic manner of thinking, feeling, behaving, and relating to others throughout much of one's entire life. Other mental disorders are events or experiences that happen to the person during the course of his or her life, whereas a personality disorder is who that person is. A personality disorder suggests that who you are and always have been is, itself, disordered.

The FFM of personality disorder provides a more complete description of each person's self that recognizes and appreciates that the person is more than just the personality disorder and

that other aspects of the self can be adaptive, even commendable, despite the presence of some maladaptive personality traits. Some of the personality strengths may be quite relevant to treatment, such as openness to experience indicating an interest in exploratory psychotherapy, agreeableness indicating an engagement in group therapy, and conscientiousness indicating a willingness and ability to adhere to the demands and rigor of dialectical behavior therapy.

Improved Construct Validity

An additional advantage of integrating the classification of personality disorder with general personality research is bringing a considerable body of scientific knowledge concerning the assessment, etiology, course, temporal stability, important life outcomes, and other matters of construct validity to the understanding of personality disorders (Ozer and Benet-Martinez, 2006; Widiger and Trull, 2007). The weak empirical support for many of the APA personality disorder categories contributed to an initial proposal for DSM-5 to delete virtually half of them (Skodol, 2012). This was not a strong endorsement for the validity of the nomenclature.

Many of the construct validity problems for the DSM-5 personality disorders are well addressed to the extent that they are understood as maladaptive variants of the domains and facets of the FFM. For example, one of the major difficulties for the categories is their excessive diagnostic co-occurrence (Skodol, 2012). Lynam and Widiger (2001) demonstrated empirically that the extent to which the personality disorders share FFM traits explains the co-occurrence among them. An additional issue for the DSM-5 personality disorders has been their differential sex prevalence rates, which some have suggested reflects a gender bias in a respective disorder's conceptualization, diagnosis, and/or assessment (Oltmanns and Powers, 2012). The differential sex prevalence rates obtained for the personality disorders are difficult to justify in the absence of any theoretical basis for the differential sex prevalence that should be obtained. In contrast, the FFM has proved useful in explaining gender differences in personality, including the personality disorders. The differential sex prevalence rates obtained for the DSM-5 personality disorders are in fact consistent with gender differences in general personality structure (Widiger et al., 2013).

FFM and DSM-5

Section III of DSM-5, for emerging models and measures, includes a five-domain dimensional trait model that aligns closely with the FFM. As stated in DSM-5, the five domains are "maladaptive variants of the five domains of the extensively validated and replicated personality model known as the 'Big Five,' or the Five-Factor Model of personality" (APA, 2013: 773). DSM-5 *Negative Affectivity* aligns with FFM neuroticism, *Detachment* with FFM introversion, *Antagonism* with FFM antagonism, *Disinhibition* within FFM low conscientiousness, and *Psychoticism* or *Peculiarity* with FFM openness. Within these five broad domains are 25 relatively more specific traits. For example, included within the domain of negative affectivity are emotional liability, anxiousness, separation anxiety, hostility, and depressivity. The assessment of these 25 traits is essentially equivalent to Step Two of the FFM of personality disorder four-step procedure for personality disorder diagnosis.

The diagnostic criterion sets for the personality disorder types included in Section III of DSM-5 consist of a combination of level of personality functioning with maladaptive personality traits (APA, 2013). For example, the diagnosis of DSM-5 Section III BPD includes an assessment of the traits of anxiousness, separation insecurity, hostility, depressivity, impulsivity, emotional liability, and risk taking. These traits align closely with those included with the FFBI assessment of BPD (Mullins-Sweatt et al., 2012), including anxious uncertainty (a maladaptive variant of FFM anxiousness), dysregulated anger (the BPD variant of FFM angry hostility), despondence (FFM depressiveness), behavioral dysregulation (FFM impulsivity), affective dysregulation (FFM vulnerability), and rashness (low FFM deliberation). As noted below, however, the FFM conceptualization of BPD includes additional traits (i.e., self-disturbance, fragility, dissociative tendencies, distrustfulness, manipulativeness, and oppositional).

There are, however, some differences between FFM of personality disorder diagnosis and DSM-5 Section III. These include the absence of normal traits, a limited recognition of bipolarity within the trait structure, and a relatively narrow list of abnormal traits. Each of these differences will be discussed briefly in turn.

Absence of Normal Traits

Normal personality traits were considered for inclusion within DSM-5, consistent with the original name of the work group as the Personality and Personality Disorders Work Group (Skodol, 2012). However, it eventually became apparent that no such traits would be included. All of the 25 DSM-5 traits refer to abnormal personality, as do the five domains (APA, 2013). Each DSM-5 Section III domain is scored on a four-point scale, where 0 = very little or not at all, 1 = mildly descriptive, 2 = moderately descriptive, and 3 = extremely descriptive. Having very little antagonism does not imply being agreeable. It just means being only a little bit antagonistic. There is no ability within the DSM-5 dimensional trait model to assess personality strengths.

Limited Recognition of the Bipolarity of Maladaptive Personality Structure

The five domains of the DSM-5 dimensional trait model are unipolar; that is, low scores on each domain suggest the absence of the maladaptive traits. Low scores do not indicate the presence of traits that are opposite to those at the high end. This is in stark contrast to the FFM, as the latter includes maladaptive variants at both ends of each pole. For example, in the FFM, opposite to antagonism is agreeableness, which includes such maladaptive traits as gullibility, meekness, subservience, self-denigration, and selflessness (see **Table 1**); opposite to disinhibition is constraint, or conscientiousness, including such maladaptive variants as perfectionism, workaholism,

rigidity, and doggedness. The DSM-5 dimensional model, however, does not include traits for maladaptive extraversion, agreeableness, low neuroticism, or low openness (and only one for conscientiousness: rigid perfectionism).

There is a considerable body of research to support the bipolarity in the structure of abnormal personality traits (Widiger et al., 2012). Equally important, the absence of the bipolarity in DSM-5 contributes to a number of problems, including the failure to include some important traits and the misplacement of others. For example, because the model does not include maladaptively low neuroticism (low negative emotionality), DSM-5 Section III is unable to acknowledge the existence of psychopathic fearlessness and glib charm (Lynam and Widiger, 2007). Because the model doesn't include maladaptive agreeableness, there is no ability to recognize dependent self-denigration, gullibility, and meekness.

The absence of bipolarity also results in some of the trait misplacements. For example, submissiveness is a manner of interpersonal relatedness that is associated with agreeableness, but in the absence of acknowledging any maladaptive agreeableness it was placed instead within negative affectivity. Attention-seeking is classified in DSM-5 as a facet of antagonism, inconsistent with the FFM research that places it within extraversion. Perseveration is a trait of compulsivity, but in the absence of conscientiousness it is placed within negative affectivity.

There is some effort within the DSM-5 to acknowledge the existence of the bipolarity. For example, DSM-5 includes a specifier for psychopathic fearlessness, to be indicated by low scores on anxiousness (APA, 2013). However, low maladaptive anxiousness does not necessarily suggest the presence of its opposite, maladaptive fearlessness. Maladaptive anxiousness is said to involve intense feelings of nervousness, tenseness, feeling fearful, apprehensive, and fears of falling apart, losing control, or embarrassment. Measures of anxiousness will correlate significantly with measures of fearlessness, but it is evident that the absence of maladaptive anxiousness does not necessarily suggest the presence of fearlessness.

Limited Number of Traits

Even for the FFM domains that are included, such as antagonism and neuroticism, the proposed model for DSM-5 is limited in its coverage. This is due in part to the fact that the original selection of traits was not based on a systematic survey of the clinical or research literature, nor on the basis of an effort to represent alternative dimensional trait models. The original list of 37 traits was a result of nominations by members of the DSM-5 Work Group, and it was subsequently pared down to just 25 through a factor analysis (Krueger et al., 2011).

Missing from the DSM-5 Section III dimensional trait model are such traits as workaholism, aggressiveness, shamefulness, rumination, vanity, entitlement, fearlessness, meekness, glib charm, and selflessness. The lack of full coverage is particularly evident when one considers the traits that are available for the diagnosis of respective DSM-5 personality disorders. For example, narcissistic personality disorder is diagnosed by just the two traits of grandiosity and attention-seeking; obsessive-compulsive by just rigid perfectionism, perseveration, restricted affectivity, and intimacy avoidance; and dependency by just submissiveness, anxiousness, and separation insecurity.

The limited number of traits and the lack of recognition of the bipolarity of maladaptive personality structure within DSM-5 Section III are perhaps understandable. There has been strong opposition to the dimensional trait model approach to the conceptualization and diagnosis of personality disorder (e.g., Shedler et al., 2010), and a common criticism of the FFM is that it will be too complex for clinicians to use. Opponents to the dimensional trait model would have had a ready target if the authors of the DSM-5 trait model had proposed the entire FFM model. Any model that provides a comprehensive description of normal and abnormal personality structure will be necessarily complex, at least at the facet level. An initial shift to a dimensional trait model should perhaps first propose a simplified version that would be more readily acceptable.

Conclusions

The FFM of personality disorder provides a reasonably comprehensive integration of normal and abnormal personality within a common hierarchical structure. Advantages of the FFM of personality disorder include the provision of precise, individualized descriptions of the personality structure of each patient, the inclusion of homogeneous trait constructs that will have more specific treatment implications, and the inclusion of normal, adaptive personality traits that will provide a richer, fuller, and more appreciative description of each patient. The FFM of personality disorder would address the many fundamental limitations of the categorical model (e.g., heterogeneity within diagnoses, inadequate coverage, lack of consistent diagnostic thresholds, and excessive diagnostic co-occurrence), and bring to the nomenclature a wealth of knowledge concerning the origins, childhood antecedents, stability, and universality of the dispositions that underlie personality disorder. It is apparent that DSM-5 is shifting closer to the FFM through the inclusion within Section III for emerging models and measures a five-domain dimensional model that aligns closely with the five factors of the FFM.

Abstract

The Five-Factor Model (FFM) is a language-based model of the structure of personality. Evidence from three lines of research on the FFM's universality across cultures is reviewed: (1) questionnaire studies that sought to replicate the FFM across cultures; (2) psycholexical studies that examined implicit models of personality in different languages using lexica; and (3) indigenous and emic–etic studies that examined personality structures in specific cultures using a variety of methods, and subsequently assessed the overlap between these models and the FFM. Support for the universality of the FFM is strongest when FFM-based questionnaires are used and tends to be stronger in Western than in non-Western cultures. Four factors are usually well replicated (Neuroticism, Extraversion, Agreeableness, and Conscientiousness), whereas the fifth factor, Openness, is not always found. From a psycholexical perspective, the replicability of three broad dimensions is best established: Extraversion, Agreeableness, and Conscientiousness. Emic–etic studies tend to converge on a structure similar to the FFM, although sometimes expanding it in the domain of social-relational functioning. The nonreplication of the FFM cannot be easily attributed to a common pattern of causes; data quality, availability of abstract terms in the language, and cultural salience of the concepts are often involved.

The Five-Factor Model (FFM) of personality is a model of the structure of personality firmly based in language, according to which human personality can be described using five broad dimensions: Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness. Each of these dimensions subsumes a number of lower level traits on both the positive and the negative pole, for example, *talkative* and *reserved* in Extraversion, *friendly* and *harsh* in Agreeableness, *orderly* and *messy* in Conscientiousness, *calm* and *fearful* in Neuroticism, and *perceptive* and *ignorant* in Openness (Goldberg, 1990). The terms *Five-Factor Model* and *Big Five* are often used interchangeably, although in the narrow sense, the former refers to a stricter version of the model with 30 definite lower level facets (Costa and McCrae, 1992), whereas the latter encompasses a broader array of models with different lower level components; we follow the habit of using the two terms as synonymous.

The FFM was initially developed to provide a parsimonious account of variation in personality descriptions in the English language. The FFM dates back to work by Allport and Odbert (1936) and Stagner (1937) in the 1930s, revived in the 1960s by Norman (1963) and Tupes and Christal (1961), and widely established in the last decades of the twentieth century by various researchers, notably Goldberg (1990) and McCrae and Costa (1997). This renewed interest spurred cross-cultural studies of the FFM, turning the attention toward the cross-cultural replicability of the model. If the FFM were found to replicate across cultures and languages, this would provide support for its validity as a panhuman model of personality and would allow it to be used as a basis for theorizing and empirical research transcending cultural and regional boundaries. In parallel developments, research on animal personality has identified personality components that could be interpreted in terms of (subsets of) the FFM in animals, whereby most overlap was found in humans' closest relatives, chimpanzees (Gosling and John, 1999).

To what extent is there a single, species-wide model of personality in humans? The positions taken on this question vary. Historically, the discussion goes back to the emic–etic distinction, introduced by Pike (1967). 'Etic' refers to research that studies cross-cultural differences from a comparative perspective (studying each individual culture less profoundly), whereas 'emic' refers to research that examines a specific culture in more detail with no (or only a secondary) cross-cultural focus. An etic, universalistic, perspective in personality can be found in five-factor theory (McCrae and Costa, 2008), where the dimensions of personality are assumed to be biologically based and universal, whereas specific manifestations of the model's components are shaped by culture. From a more relativistic perspective, personality can only be understood in cultural and historical context (Piekkola, 2011). There are methodological approaches, such as the psycholexical approach (discussed in a following section), which have no a priori position on the universality of the FFM or other models, but provide important tools for addressing the topic. Finally, there are theoretical and methodological approaches, labeled *emic–etic* (Cheung et al., 2011), that seek to combine universalistic and relativistic approaches. Emic–etic approaches seek to integrate evidence on more universal and more culture-specific elements in personality models.

We review the empirical evidence on the FFM accumulated from three lines of research: (1) questionnaire studies that sought to replicate the FFM across cultures; (2) psycholexical studies that sought to establish implicit models of personality in different languages using lexica; and (3) indigenous and emic–etic studies that sought to establish personality structures in specific cultures using a variety of methods, and subsequently assess the overlap between these models and the FFM. In the first two sections, we start from the evidence in support of FFM universality and progress toward divergent evidence, while also commenting on methodological limitations and

shortcomings. In the final section, we present findings on indigenous concepts and their degree of overlap with the FFM in several non-Western cultures.

Questionnaire Studies

In the questionnaire study design, participants respond to a list of questions about their typical characteristics, behaviors, feelings, and thoughts. Items include abstract trait terms (e.g., 'I am talkative') as well as behavioral terms (e.g., 'I make friends easily'). Responses are factor-analyzed, and the resulting structure is compared with an existing factor structure, typically derived from US data. Statistical criteria are used to evaluate agreement by using congruence coefficients that indicate the degree of equivalence between the two structures (interpreted as supportive evidence for the identity of factors across the cultures studied). Congruence coefficients of .95 and higher indicate equivalent structures (Lorenzo-Seva and Ten Berge, 2006; Van de Vijver and Leung, 1997), although values of .85 or higher are sometimes also taken as evidence of similarity. A similar procedure can be used to compare individual-level to country-level factor structures (Van de Vijver and Poortinga, 2002).

The most popular inventory for measuring the FFM is the Revised NEO Personality Inventory (NEO-PI-R; Costa and McCrae, 1992), which measures 5 broad domains and 30 lower level facets, 6 per domain (i.e., the FFM in the narrow sense, mentioned in the Introduction). Another popular instrument is the Big Five Inventory (BFI; John et al., 1991). Both instruments have been translated into a large number of languages from different families, using back-translation procedures. The self-report form of the NEO-PI-R has been administered in 36 cultures (McCrae, 2002), and the peer-report in 50 cultures (McCrae, Terracciano, and 78 Members of the Personality Profiles of Cultures Project, 2005a). The BFI has been administered in 56 cultures (Schmitt et al., 2007). All these studies tended to find fair to very good replicability of the factors of the FFM in individual cultures and for the total set of cultures compared with the US structure. The general replicability between the individual- and culture-level factor structure, together with evidence for the external validity of culture-level scores (e.g., their associations with cultural values and economic indices), has enabled researchers to construct 'personality profiles' of cultures (McCrae, Terracciano, and 79 Members of the Personality Profiles of Cultures Project, 2005b) and to explore the geographical distribution of Big Five traits (Schmitt et al., 2007). For example, Schmitt et al. (2007) found that average levels of Extraversion were lower in East Asia than in other regions. Finally, broad support for the replicability of the FFM has also been found in studies with less extensive culture coverage, both using other instruments designed to measure the FFM (Caprara et al., 2000; De Fruyt et al., 2009; Hendriks et al., 2003) and using instruments that had not been initially devised as a measure of the FFM, including nonverbal instruments (Paunonen et al., 1996).

Several limitations on the support for the universality of the FFM from questionnaire studies require attention. First, although the five factors generally tend to replicate, not all replications pass accepted thresholds for construct equivalence (Lorenzo-Seva and Ten Berge, 2006; Van de Vijver and Leung, 1997). More discrepancies tend to be found at lower levels of aggregation (i.e., for individual countries and country regions) than for global solutions. In McCrae et al. (2005a), there were a number of non-Western, especially African, countries with congruence coefficients below .80, especially for Openness. The authors attributed the finding to shortcomings in data quality rather than insufficiency of the model for these countries. In Schmitt et al. (2007), several coefficients especially in Africa and South and Southeast Asia were below .90, with the lowest one of .84 for Openness in Africa. Second, although the culture-level five factors map fairly closely on the individual-level factors, the two structures are not identical. On culture level, Extraversion was codefined by a number of facets from other factors (McCrae et al., 2005b), and the correlations between the NEO-PI-R and BFI factors were less supportive of the convergent and discriminant validity of the factors than on individual level (Schmitt et al., 2007). The implication is that interpretations of individual differences cannot be transferred simply to interpretations of country mean differences. Third, although the structural equivalence of the five factors on individual level has broadly been established, there is no comparable support for measurement equivalence but there is some evidence for inequivalence (Church et al., 2011). The implication is that direct numerical comparisons of trait scores across cultures are not yet warranted: Individual differences in the five factors do not have the same meaning across countries. Fourth, the questionnaire study design has the inherent limitation that it can only be used in a straightforward manner in literate populations. Most of the studies have been conducted on student samples. In one of the rare studies on preliterate societies, Gurven et al. (2013) failed to replicate the FFM using the BFI. The authors interpreted their finding as evidence that the FFM may not be applicable to the Tsimane ethnic group in the Bolivian Amazon and likely to other small-scale, preliterate societies; a more conservative interpretation would involve issues of method bias and inadequacy of questionnaire adaptation. Finally, an inherent limitation of questionnaires is that they tend to impose structure on the data to a certain extent (Church, 2000). Support for cross-cultural replicability has been obtained also for other models, measured with respective questionnaires, such as the Eysenck Personality Questionnaire (EPQ; Barrett et al., 1998). While questionnaires offer a powerful tool for replicating factor structures, they are less efficient as tools for discovering factors implicit in different cultures and languages. Such instruments cannot address the question whether the items are the best possible rendering of personality in that culture and whether culture-specific aspects were not left out.

Psycholexical Studies

Research in the psycholexical (or *lexical*) tradition is based on the assumption that the most important features of personality become encoded as single terms in language ('psycholexical hypothesis'; Goldberg, 1981). Single personality-descriptive terms can be derived from lexica and subsequently reduced through content and factor analysis to arrive at a few broad dimensions of personality. A lexical study begins with an exhaustive extraction of personality terms from current

dictionaries. In the stricter and more common version of the approach, only terms referring to internal psychological characteristics are selected, whereas terms that are purely evaluative, refer to physical appearance, beliefs, temporary states, or do not describe personality are excluded (Saucier, 2008). The list is further shortened by selecting the terms that appear most frequently in natural language usage. Participants are presented with the selected trait list and asked to assess to what extent each term is applicable to them (or to a target person they know well). The scores of the participants are factor-analyzed, resulting in models with a few dimensions that account for the covariation of trait terms. Because of the comprehensive selection of trait terms, this approach is less restrictive than the questionnaire approach in the dimensions it can identify and is thought to be more representative of the implicit structure of personality in each language.

The Big Five model was first identified in the outcomes of lexical research in English (Goldberg, 1990). Lexical studies have since been conducted in about 15 other Indo-European as well as non-Indo-European languages. Direct empirical comparisons and conceptual overviews of the lexical data across languages have not converged on a single model replicable across languages (De Raad et al., 2010; Saucier, 2008). Although factors similar to those of the Big Five have been identified across languages, the Big Five as a coherent structure defined by common elements has only been replicated in the Germanic languages (Saucier and Goldberg, 2001). In an analysis on data from 12 languages obtained according to the common premises (e.g., full rather than random extraction of terms, exclusion of purely evaluative terms), with explicit definition of common terms defining factors, and direct psychometric assessment of structure equivalence (with a liberal cutoff value for congruence coefficients at .80), De Raad et al. (2010) found that only three factors were fully replicable across languages: Extraversion, Agreeableness, and Conscientiousness. These factors were more broadly defined than the corresponding Big Five factors because they included terms from the other factors. These three factors tend to be the three largest factors in lexical studies. There is less agreement across languages on factors beyond these three.

Some limitations of the psycholexical approach are effected from the opposing aims of arriving at a common model for implicit personality concepts across languages while providing a comprehensive representation of these concepts. The first aim drives research toward the identification of fewer personality factors, whereas the second drives research toward more factors (De Raad et al., 2010). Comparability of factors across languages is challenged by procedural differences between studies with respect to the selection of data sets and of terms to be analyzed, item translation, and decisions regarding factor extraction and rotation. In addition, there is the more important limitation that different sets of items provide the input for the analyses in different languages. The factors are usually defined by a limited number of highly loading items, called *markers*. These markers tend not to overlap across languages, and decisions have to be made as to which markers to use for factor identification and subsequent comparisons. These decisions can be biased by prior expectations, for example, of retrieving the Big Five factors. A classic example is that of Assertiveness terms. In the English Big Five structure, Assertiveness is a facet of the first factor, Extraversion. When, in other languages, Emotional Stability fails to emerge as a fourth factor, Assertiveness terms loading on the fourth factor can be taken to indicate Emotional Stability because this is the expected factor. Such interpretations amount to circular reasoning in assuming what has to be shown (De Raad and Peabody, 2005).

A different set of limitations apply to the conceptual premises of the psycholexical approach. Although it is reasonable to expect that trait terms are used universally, it has not been established that they are equally frequent across languages and perceived as equally informative of personality across cultures. There is evidence that abstract trait terms are used more often in personality descriptions in Western groups, whereas specific behavioral descriptions are preferred in non-Western groups (Del Prado et al., 2007; Valchev et al., 2013). It may also be the case that some personality domains are less saturated with single abstract trait terms, which could explain the weak replicability of the smaller factors, Neuroticism and Openness, in lexical studies as opposed to questionnaire studies. In more practical terms, the psycholexical approach is not directly applicable to languages where there are wide variations between a common written language and spoken dialects, as in Arabic, and to languages that have no developed lexicography.

Indigenous and Emic–Etic Studies

In contrast to the etic studies that seek to replicate personality structure across cultures, such as the NEO-PI-R replicability studies, indigenous or emic studies focus on the identification of personality concepts perceived as relevant in specific, typically non-Western cultures. Emic studies employ an array of methods including psycholexical methods, ethnographic interviews, and reviews of folklore and literature for personality characteristics. The strength of this kind of research is in the comprehensive representation of the implicit personality models, not bound by questionnaire item selections or exclusive reliance on lexical records.

There is some work on individual, purely indigenous (emic) personality concepts, such as the East-Asian, religion-based selfless self (Ho, 1995) and the Japanese Amae (Doi, 1973). However, this work has never developed into full-fledged personality models. When the personality concepts derived in indigenous research are compared with those from other cultures or with supposed universal models, more confident conclusions on the generalizability and universality of personality concepts can be drawn. Some of the major findings from indigenous research in different parts of the world are presented below.

In the Philippines, indigenous research has identified a number of implicit personality dimensions represented in different models (Guanzon-Lapeña et al., 1998). Katigbak and colleagues (Katigbak et al., 1996, 2002) examined the indigenous dimensions jointly with the FFM and found that most indigenous concepts could be subsumed in the FFM. There were only a few concepts that were not empirically encompassed by the FFM, such as social curiosity, risk-taking, and religiosity (Katigbak et al., 2002). Importantly, the indigenous

concepts offered only modest incremental criterion validity above the FFM.

In Mexico, Ortiz et al. (2007) reviewed previous literature on indigenous concepts and examined the relations of a large number of indigenous measures with the FFM. They found that most of the Mexican concepts could be well subsumed within the FFM. Concepts of warmth and affection appeared to be more salient in the indigenous measures, whereas Openness could not be identified in the indigenous measures but only in the imported FFM measures. Overall, both in the Philippines and in Mexico, researchers were led to conclude that cultural differences may not be expressed in the clear identification of dimensions beyond the Big Five, but rather in the salience and composition of elements that can all be subsumed in the Big Five.

In China, several independent lines of research have explored the indigenous structure of personality (reviewed in Yang, 2006). The best established questionnaire that resulted from one of these lines of research is the Cross-Cultural (initially Chinese) Personality Assessment Inventory (CPAI-2; Cheung et al., 2003). Developed with input from interviews and reviews of wide-ranging literature sources, this inventory identified one dimension that could not be subsumed within the FFM, Interpersonal Relatedness, which involves aspects of functioning in social context and adherence to tradition. Subsequent studies have replicated the Interpersonal Relatedness factor in non-Chinese populations, including the US (Lin and Church, 2004), suggesting that although Interpersonal Relatedness is most salient in China, it is not unique to China but is recognizable in other cultures. Openness, on the other hand, has not been identified in China using indigenous measures but only using imported measures (Cheung et al., 2008). So, although single concepts referring to Openness are used in the Chinese context, they are not implicitly recognized as constituting a coherent personality dimension. This pattern is opposite to that of Interpersonal Relatedness. Finally, it is noteworthy that the Interpersonal Relatedness dimension has been found to offer incremental validity in the prediction of culturally relevant outcomes in China (Cheung, Cheung, and Fan, 2013; Zhang and Bond, 1998).

In South Africa, a culturally heterogeneous country with 11 official languages, recent indigenous research has identified nine clusters of personality concepts derived from free personality descriptions (Nel et al., 2012). All of the Big Five factors were recognizable within the nine clusters, but the nine clusters included a large number of concepts dealing with interpersonal relations. This finding is consistent with findings from lexical and other indigenous studies, where Agreeableness-related terms normally form the largest factor. The quantitative validation of the conceptual model is currently ongoing, but there are some initial indications that concepts related to social-relational functioning in a fairly norm-regulated context are salient in South Africa, yet not well covered by the FFM.

Conclusion

Support for the universality of the FFM is strongest when FFM-based questionnaires are used and tends to be stronger in Western than in non-Western cultures. Four out of the five factors are usually well replicated (Neuroticism, Extraversion, Agreeableness, and Conscientiousness), whereas the fifth factor, Openness, is not always found. From a psycholexical perspective, the replicability of three broad implicit dimensions is best established: Extraversion, Agreeableness, and Conscientiousness. The nonreplication of the FFM cannot be easily attributed to a common pattern of causes; data quality, availability of abstract terms in the language, and cultural salience of the concepts are often involved. Despite some strong proposals (e.g., Buss, 1991; McCrae and Costa, 2008), there is no commonly accepted theory of the Big Five or FFM that would account for the universal occurrence of the five factors or their causal role in behavior. In fact, the role of the Big Five factors as causal entities is periodically challenged (e.g., Cramer et al., 2012). The lack of such a commonly accepted theory can be perceived as contributing to the dangers of circular reasoning (De Raad and Peabody, 2005). Nonetheless, research on the universality of the FFM has produced invaluable data and rich insights into the patterns of similarities and differences in personality across cultures.

Flashbulb Memories

Daniel L Greenberg, College of Charleston, Charleston, SC, USA

Abstract

A *flashbulb memory* is a vivid and enduring memory for the circumstances in which one learned of a momentous public event (Brown and Kulik, 1977). For example, many people have vivid memories of the way in which they heard about the assassination of John F. Kennedy, the resignation of Margaret Thatcher, the explosion of the space shuttle *Challenger*, or the September 11th attacks. The idea has substantial appeal, and several articles in the popular media have discussed it (Berendt, 1973; Pew Research Center, 2002). Other studies, however, have shown that flashbulb memories are not as immutable as they seem. More recently, researchers have begun to focus on the phenomenological properties of these memories as well as the social and cultural factors that influence this kind of recall.

An Early Study

Colegrove (1900) conducted the first reported study of these memories. He did not refer to these as flashbulb memories (the photographic flash was not in widespread use at the time), but his methods and data clearly show that he was investigating the same phenomenon. In the course of a wide-ranging survey of memories and memory types, he asked people if they had vivid memories of how they heard about the assassination of President Lincoln over 30 years before. Here is the first example he provides:

> … When we were driving down a steep hill into the city we felt that something was wrong. Everybody looked so sad and there was such terrible excitement that my father stopped his horse, and, leaning from the carriage, called 'What is it, my friends? What has happened?' 'Haven't you heard?' was the reply – 'Lincoln has been assassinated.' The lines fell from my father's limp hands, and with tears streaming from his eyes he sat as one bereft of motion … (Colegrove, 1900: p. 263)

Colegrove (1900) acknowledges that most of the memories were not this detailed, and in fact the rest of his examples contain no more than the bare particulars. Nonetheless, he found these particulars noteworthy. He defined a vivid memory as one that contained information about the time, the location, and the informant; he found that 71% of participants (127/179) could report such a memory. Some of the remainder (Colegrove does not say how many) had a vivid memory for the assassination of President James Garfield in 1881. While this percentage might seem a bit low – after all, a flashbulb memory is of an event that 'everybody remembers' – Colegrove's (1900) data nonetheless show that many people can retain clear and detailed memories a full three decades after the original event.

The First Theory

After Colegrove (1900), the phenomenon seems to have gone unstudied (at least in the psychological literature) until 1977, when Brown and Kulik published the article that named the phenomenon. Their experiments investigated memories for a series of shocking and consequential events, including the assassination of President John F. Kennedy and Martin Luther King, Jr. In their words:

> [T]here is something strange about this recall… . Almost everyone testifies that his recall of his circumstances … has a primary, "live" quality that is almost perceptual. Indeed, it is very like a photograph that indiscriminately preserves the scene in which each of us found himself when the flashbulb was fired. (Brown and Kulik, 1977)

Brown and Kulik (1977) quickly tempered this description by noting that the memory was not quite as indiscriminate as a photograph, since many extraneous details were not in fact preserved. Rather, they suggested that flashbulb memories tended to focus on several canonical features. These included the place, the informant, and the activities that were going on at the time (as Colegrove (1900) had suggested), but also the participants' reaction, others' reactions, and the immediate aftermath. In spite of this, a memory could be classified as a flashbulb if it contained information from only one of these categories. That is, if a participant only remembered where they were, but not what they were doing, who told them, how anyone reacted, or what they did afterward, they would still be treated as having a flashbulb memory.

Brown and Kulik (1977) also attempted to identify the kinds of events that led to the formation of a flashbulb memory. First came *novelty* or surprise: the event had to be unexpected, like an assassination or a sudden eruption of scandal. Second, the event had to be seen as *consequential* for the person's life. According to their definition, consequentiality meant something distinct from personal or historical importance. Rather, consequentiality takes on something close to a biological significance; an event was defined as consequential to a person if his or her life was changed in some noteworthy way. (Brown and Kulik (1977) operationalized this property by asking people to think about how their lives would have been different if the event had not happened.) Finally, they observed that both of these factors could lead to an increased *rehearsal*: people tend to talk and think about consequential and novel events, and rehearsal can of course improve memory.

To tie all of these features together, Brown and Kulik (1977) proposed a theoretical explanation for flashbulb memories. In particular, they drew an analogy with Livingston's (1967) "Now Print!" hypothesis. They speculated that the human brain has evolved a 'special mechanism' to fix key events in memory. According to this view, under some circumstances – specifically, when an event is surprising and consequential – the special mechanism is activated and the 'flashbulb' fires; under other circumstances, it is not and does not. As Wright (2009) has suggested, this hypothesis implicitly assumes that flashbulb memories are qualitatively different from everyday memories (see Curci, 2009, for other methodological issues). That is, they are not just points on the extreme end of the vividness scale; they are a different type of memory, perhaps involving different cognitive and neural mechanisms.

Brown and Kulik (1977) maintained that this theory provided a good explanation for their data. People tended to find the assassinations and political scandals surprising, and they tended to have flashbulb memories for how they heard the news. (Note, however, that as with Colegrove's (1900) participants, not everyone had flashbulb memories for these events. In fact, fewer than half of Brown and Kulik's (1977) participants had flashbulb memories for the deaths of Malcolm X, Medgar Evers, and George Wallace.) The deaths of Martin Luther King and other civil rights leaders were presumed to be more consequential for black Americans than for white Americans, and, in at least some cases, black Americans were more likely to have flashbulb memories for these events than white people were (see Wright, 2009 for some criticisms of their data). People tended to report rehearsing these memories. Overall, Brown and Kulik (1977) seemed to have presented a plausible explanation of an intriguing phenomenon.

The 'flashbulb' metaphor is compelling for several reasons. First, from a general evolutionary perspective, it seems at least plausible that we might have a special mechanism for the creation of a vivid memory; it might help us avoid similar dangerous situations in the future. Second, while Livingston's (1967) proposal was speculative at the time, it does seem to be consistent with a substantial body of later research showing that emotional material (particularly negatively valenced material) is remembered better than neutral material. Third, the idea is consistent with our own intuitions: these memories really do seem different from other memories, we really do think and talk about them a lot, and we can rarely remember other events with such apparent clarity. In short, the idea made a great deal of sense.

Accuracy, Consistency, and Challenges to the 'Special Mechanism'

This apparently sensible proposal soon received a great deal of criticism. Specifically, contrary to the plain meaning of the metaphor, flashbulb memories are not extraordinarily accurate or consistent. Note that accuracy and consistency are not the same, nor are they necessarily correlated. A memory can be consistent without being accurate, as when we remember the same inaccurate information over and over again. Counterintuitively, a memory can also be accurate but not consistent, depending on how one measures accuracy (see Julian et al., 2009 for further discussion). Suppose that a student heard about the September 11th attacks while sitting in a psychology class and sending a text message to a friend. Upon first recalling the event, the student only reports sitting in class. At the second recall, only the text message is reported. The memories are entirely inconsistent, but they are accurate (albeit incomplete). We know relatively little about the accuracy of flashbulb memories, since researchers are rarely collecting data when the original event happens. At best, we can identify a few cases in which the memory could not have happened as remembered (Linton, 1975; Neisser, 1982; Greenberg, 2004).

Consistency is somewhat easier to measure. Neisser and Harsch (1992) reported inconsistencies in flashbulb memories for the Space Shuttle *Challenger* disaster, as did McCloskey et al. (1988). Talarico and Rubin (2003) compared flashbulb memories for 9/11 to memories of noteworthy personal events that had taken place the week before; they found that flashbulb memories were no more consistent than the personal memories, though participants did have greater confidence in the accuracy of the flashbulbs. Schmolck et al. (2000) showed that memories for the verdict in the O.J. Simpson trial were inconsistent over time. Crombag et al. (1999) showed that participants could falsely remember nonexistent footage of a plane crash. Greenberg (2004) reported that President Bush had done the same for the September 11th attacks. Neisser (1982) observed that his own recollection of Pearl Harbor was inaccurate (see Thompson and Cowan, 1986; Neisser, 1986, for discussion). Researchers do not agree about the degree of inconsistency in flashbulb memories, in part because almost every study uses a different measurement method. Nevertheless, the majority of the evidence suggests that some degree of inconsistency exists.

Furthermore, flashbulb memories seem to be susceptible to the same kinds of errors as other memories. Neisser and Harsch (1992) found that many people came to believe that they had learned about the *Challenger* disaster on television, even though they originally stated that they had heard about it another way. For example, one participant originally reported that she overheard people talking about it in her religion class; 2 years later, she claimed that she learned about it while watching TV with her roommate. Neisser and Harsch (1992) called this phenomenon 'TV priority' and suggested several possible reasons for it. For one, most if not all of the participants did see the news on television at some point. The TV coverage was particularly compelling; the image of the exploding shuttle was played over and over, creating a memory that was far more coherent and vivid than the original circumstances (see Figure 1 for the iconic image of the event).

This is an example of a 'wrong time slice' error (Brewer, 1988); participants remembered something that actually happened, but mislocated it in time. Similarly, Neisser and Harsch (1992) suggested that the participants might have been relying on a script or schema for learning about shocking events. That is, people typically learn events by learning about them on television (or, in today's world, the Internet), so they look for such memories when trying to reconstruct how they themselves heard the news. In short, flashbulb memories seem to be susceptible to the same sorts of errors as everyday memories.

Figure 1 Many people have a flashbulb memory for the explosion of the space shuttle *Challenger*. Source: National Aeronautics and Space Administration (http://grin.hq.nasa.gov/ABSTRACTS/GPN-2004-00012.html).

These findings have led many researchers to reject the notion of a special mechanism. McCloskey et al. (1988), for instance, suggested that there was no reason to believe in a unique flashbulb-memory mechanism that differed from the mechanisms involved in everyday recall. Rather, the qualities of the event (the shock, the disruption of the regular routine, the personal significance, etc.) probably make the event more novel and less susceptible to interference, and these properties are a well-established part of normal memory (Cohen et al., 1988, 1990; Pillemer, 1990; Schmidt and Bohannon, 1988; Talarico and Rubin, 2009; Wright, 2009). In accordance with this view, flashbulb memories are no more vivid than the most vivid of autobiographical memories (Rubin and Kozin, 1984), and they therefore belong on the continuum of autobiographical memories, not in a category of their own.

Beyond the Special Mechanism

For many researchers (though not all), flashbulb memories still merit investigation even if no special mechanism exists. Talarico and Rubin (2007, 2009) have suggested that the phenomenology of flashbulb memories is unusual, even if the consistency is not (Rubin and Kozin, 1984). In fact, flashbulb memories are interesting in part precisely because the phenomenology and the consistency diverge (Talarico and Rubin, 2003). In addition, one can examine the factors that lead to the development of flashbulb memories, whether or not they are accurate or consistent. Many studies have been conducted along these lines, and several of them have further challenged the proposals that Brown and Kulik (1977) originally made.

Novelty and Surprise

Several models of flashbulb memory have suggested that novelty and surprise are important features (Brown and Kulik, 1977; Conway et al., 1994; Finkenauer et al., 1998; Er, 2003; see Luminet, 2009, for a review). As Talarico and Rubin (2009) have argued, novelty and surprise are not the same – surprise is an emotional reaction, whereas novelty is a property of the event itself – though not all models draw a clear distinction between the two. Overall, the evidence clearly shows that flashbulb memories still occur for long-anticipated and therefore unsurprising events, such as the moon landing (Winograd and Killinger, 1983), the death of former French president François Mitterand (Curci et al., 2001), the US invasion of Iraq in 1991 (Weaver, 1993), and the death of Pope John Paul II (Tinti et al., 2009). Surprise may increase the likelihood of the formation of a flashbulb (Pillemer, 1984; Christianson, 1989; Davidson and Glisky, 2002), though not always (Otani et al., 2005; Berntsen and Thomsen, 2005). In short, surprise is not required for the formation of a flashbulb memory, though in some cases it does seem to help.

Emotional Valence

Almost by definition, most flashbulb-memory events are emotionally intense. Emotional valence, however, is a different matter. Most flashbulb events are negative – assassinations, accidents, natural disasters, and the like. Yet a small body of evidence suggests that positive events can lead to flashbulb memories as well. Bohn and Berntsen (2007) examined flashbulb memories for the fall of the Berlin Wall. This event was certainly momentous, but it was interpreted in different ways by different people: some saw it as a great moment for freedom, whereas others were worried about what the future might hold. They found that both groups of people had flashbulb memories for the fall, but flashbulbs were more common in the group who viewed it as positive. Similarly, Berntsen and Thomsen (2005) found that many Danish participants had flashbulb memories for the liberation of Denmark in World War II, and that people who were part of the resistance movement were more likely to have flashbulbs. Thus, both positive and negative events can lead to the development of flashbulb memories.

Consequentiality

As noted above, Brown and Kulik (1977) defined consequentiality in a very specific way: a consequential event was one that had a notable impact upon a person's life. Traumatic events, such as an assault or the death of a loved one, are consequential almost by definition; these events had direct effects upon the individual and likely changed the course of his or her life. Flashbulb memories are not necessarily so consequential: the explosion of the space shuttle *Challenger*, while shocking and upsetting, did not change the lives of most of the people who were alive at the time (with the obvious exception of the relatives and acquaintances of the deceased, including the students of the schoolteacher who died in the explosion). Similarly, the deaths of political figures, whether surprising or not, do not necessarily have a significant effect on an individual's life (see Neisser, 1982; Berntsen, 2009, for discussion). This is a first strike against the consequentiality hypothesis: like surprise, it seems to be unnecessary for the formation of a flashbulb.

Does consequentiality have any effect at all? Evidence for its importance is mixed, in part because different researchers have defined the property in different ways. For instance, Neisser et al. (1996) examined memories for the 1989 earthquake in Loma Prieta, California. They compared three groups of participants: residents of Santa Cruz, California (for whom the effects were severe), residents of Berkeley, California (who felt the earthquake, but were at a greater distance from the epicenter), and residents of Atlanta, Georgia (who were on the other side of North America and did not feel the earthquake at all). They found that the residents of Santa Cruz had more detailed memories than the residents of Berkeley, who in turn had better memories than the residents of Atlanta. Moreover, Atlanta residents who had some connection to California (relatives, friends, and the like) had more detailed memories than Atlanta residents who did not.

By itself, this evidence seems consistent with the consequentiality hypothesis: people whose lives were influenced – whether by experiencing the earthquake or knowing someone who might have been affected – had better memories than those who did not. Yet Neisser et al. (1996) disagree. In part, their disagreement seems to be with the whole idea of consequentiality: they observe that "[al]though the fact that an assassination or resignation [or, presumably, an earthquake] has occurred may have real consequences for citizens of a given country … the occasion on which they heard about it surely does not" (Neisser et al., 1996: p. 353). While this is true enough, the objection seems to miss the point of Brown and Kulik's (1977) original claim. They argued that if the event itself was consequential, it would trigger the retention of the reception circumstances; the circumstances themselves did not have to have any significant consequences at all. Thus, while Neisser et al. (1996) suggested that consequentiality was unimportant, it is not clear that this argument speaks to the specific claim that Brown and Kulik (1977) were making. More convincing is their finding that their participants did not find the earthquake to be maximally frightening or worrisome, and that people were more worried by catastrophes happening elsewhere (such as the collapse of the Bay Bridge).

Other studies have suggested that consequentiality has little or no effect on flashbulb-memory formation. Er (2003) conducted a study of flashbulb memories for the Marmara earthquake in Turkey. The results showed that the consequentiality of the earthquake (defined as how much it changed the participants' lives) had an indirect and inconsistent association with the formation of a flashbulb memory. Similarly, Berntsen and Thomsen (2005) found that consequentiality had no effect on the accuracy of responses to questions about World War II.

Significance

An event can be personally significant or personally relevant even if it is not consequential. The death of a prominent politician might have no particular objective consequences for an individual's life, but it could still be personally relevant if it affects one's national or cultural identity (see Berntsen, 2009, for discussion). Several studies have shown that significance has a key role in the development of flashbulb memories. Conway et al. (1994) studied memories for the resignation of UK Prime Minister Margaret Thatcher and found that residents of the United Kingdom were more likely to have flashbulb memories than nonresidents (see Pezdek, 2003, for a similar study of the September 11th attacks). Similarly, even if Neisser et al.'s (1996) study shows nothing about consequentiality, it still suggests that personal relevance has an important role to play. Though there have been a few exceptions (Davidson and Glisky, 2002), the majority of studies have confirmed the fundamental – and fundamentally unsurprising – finding that people are more likely to remember events that they find important.

Narrative and Rehearsal

Several authors, including Brown and Kulik (1977) have noted that flashbulb memories are often remembered as narratives or coherent stories, and that these narratives are regularly rehearsed. Neisser et al. (1996) argued that there were several reasons for rehearsal, including social demands and a desire for self-promotion. They noted that participants reported that they had frequently thought or talked about their memories (Pennebaker and Harber, 1993). Several other studies have found a link between rehearsal and flashbulb-memory formation (Bohannon, 1988), though as Neisser et al. (1996) observed, it is difficult to know whether participants can accurately report the frequency of rehearsal.

Hirst and Meksin (2009) expanded on this view by observing that the news media provide a substantial impetus for rehearsal. In fact, in many ways, the media virtually compel rehearsal: after a flashbulb event, one can hardly watch the news or walk into a store without encountering a reminder of what has just happened. They presented data showing that the maintenance of a flashbulb memory was correlated with the frequency of news coverage of the event: declines in media coverage for both the *Challenger* disaster and the September 11th attacks were associated with declines in performance.

Sociocultural Factors

Why do we rehearse and relate these narratives? Several authors have observed that flashbulb memories seem to serve a social purpose: people seem to want to tell these stories, and a number of articles have been devoted to chronicling the ways in which famous people learned the news (Berendt, 1973). Brown and Kulik (1977) mentioned this phenomenon in their paper, suggesting that their readers were "primed with an account of [their] own, which [they] would rather like to tell" (Brown and Kulik, 1977).

Neisser (1982) has suggested that flashbulbs are significant because they help us place ourselves in history:

> The flashbulb recalls an occasion when two narratives that we ordinarily keep separate – the course of history and the course of our own lives – were momentarily put into alignment … . We remember the details of a flashbulb occasion because these details are the links between our own histories and 'History.' (Neisser, 1982: pp. 72–73)

In his terms, flashbulbs serve as 'benchmarks' that signal our place in history, and they are compelling for that reason.

Berntsen (2009) suggests that social identity plays a fundamental role in the development of flashbulb memories. According to her view, flashbulb memories serve as a way to connect us with a particular social group. Thus, her flashbulb memory of the death of the Danish king plays a role in her identity as a Dane, and my flashbulb memory of hearing about the *Challenger* disaster plays a role in my identity as an American. This identification occurs even though neither event had any significant effect on our everyday lives. By contrast, the 2003 Iranian earthquake had no connection to either of our social identities, and neither of us has a flashbulb memory for it. (Danes or Americans of Iranian descent might, of course, have a different experience.)

Furthermore, these memories allow us to connect with multiple social groups (or subsets of social groups). Americans old enough to have Pearl Harbor memories do not just identify as Americans; they can also identify as members of the World War II generation, whereas younger Americans cannot. To put this another way, people who do not share your flashbulb memories are excluded from one of the social groups to which you belong, which might account for the (admittedly anecdotal) observation that people find it jarring to encounter people who are too young to have a flashbulb memory of a particular event.

As Berntsen (2009) notes, this idea could help explain several of the results described above. Several researchers found that physical proximity or personal significance were associated with stronger flashbulb memories (Conway et al., 1994; Neisser et al., 1996; Pezdek, 2003; Yarmey and Bull, 1978). Yet social identity might be the more important factor. If so, then expatriate British people should have flashbulb memories for the death of Princess Diana (provided that they are still identified as British). Moreover, the strength of the flashbulb memory should in some way depend on the strength and number of social ties to the affected group: an American who also identified as a New Yorker and a Manhattanite should have stronger flashbulb memories than Americans who did not, even if the Manhattanite no longer lived there and did not know anyone affected by the attacks. In Berntsen's (2009) view, incorporating social identity into the flashbulb-memory model could help resolve the disparate results of previous studies. Specifically, she suggests that flashbulb memories could be formed through a number of routes – emotional reaction and/or subsequent rehearsal – and social identity serves as the underlying impetus for each of these.

Conclusions

What can we conclude from all of these studies? We know that people often say that they can remember the circumstances in which they learned of a momentous event, such as the September 11th attacks. These memories are vivid, and they are also enduring – people claim to be able to recall them decades later (Colegrove, 1900; Berntsen and Thomsen, 2005). People tend to be very confident in their memories; nevertheless, they are not necessarily accurate or consistent (though sometimes they are). The consequentiality of an event does not seem to matter very much, but the personal significance (usually) does. They can cover both positive and negative events. They are best seen as extreme instances of normal memory processes, not as the products of a special mechanism.

These conclusions might seem inconsistent or frustrating, but they reflect the significant difficulties involved in working with real-world events. There is no way to obtain control over the events themselves, and even two similar events can differ in many significant ways. As an example, the explosion of the space shuttle *Challenger* seems to be a prototypical flashbulb event (Bohannon, 1988; Bohannon and Symons, 1992; Neisser and Harsch, 1992; Terr et al., 1996; see Figure 1). The explosion of the space shuttle *Columbia* is not – or at least only a few published studies seem to have addressed it (Julian et al., 2009; Kershaw et al., 2009). Why is this so? Perhaps the second explosion was less novel or surprising given that one shuttle had already exploded. Perhaps people felt more of an emotional connection to the first explosion because a schoolteacher was on board. Perhaps it was overshadowed (for researchers as well as participants) by the September 11th attacks. Perhaps there were social-identity difference as well – perhaps the space program was no longer as important to people because the Cold War 'space race' was effectively over. Through further examinations of all of these factors, we may be able to gain more insights into this ever-intriguing phenomenon.

Flow in Motivational Psychology

Jeanne Nakamura and Matthew Dubin, Claremont Graduate University, Claremont, CA, USA

Abstract

This article describes the phenomenon of flow, the subjective experience of being completely absorbed in a task or activity. We provide an overview of the flow model of optimal experience and affirm the flow state's close association with intrinsic and emergent motivation. We also describe the various ways that flow has been measured, discuss the antecedents and consequences of flow within the domains of work and leisure, and identify emerging areas of flow research.

Introduction

Among theories of motivation, the flow model (Csikszentmihalyi, 1975/2000, 1990) is distinguished by its focus on subjective experience. In the 1960s, Csikszentmihalyi set out to study intrinsically motivated, or autotelic ('auto' = self, 'telos' = goal), activity – activity that is valued for its own sake separate from any results or rewards deriving from it. While there had been research on intrinsic motivation, no systematic empirical work had been undertaken to elucidate the *phenomenology* of intrinsically motivated activity or to situate it within the broader experiential landscape of daily life. Callois's and Huizinga's theories of play and Csikszentmihalyi's own observational research on artistic creativity and study of Continental phenomenology informed his 1975 work, which was written against the then-prevailing deterministic theories of motivation ("Beyond Boredom and Anxiety" played off of Skinner's influential title). This article describes the resulting flow model and explicates the current state of knowledge about flow.

In the initial interviews conducted in the United States by Csikszentmihalyi and colleagues, people pursuing very different potentially autotelic activities used very similar terms to describe what they experienced when things were going well. The subjective state was dubbed 'flow' because some individuals used that term in describing the fluid, focused engagement they experienced (see example, **Table 1**). The flow state's hallmark is intense involvement in which attention is complete and the person feels he or she is functioning at full capacity. In subsequent research, the experience has been described in much the same way across cultures regardless of an individual's gender, age, or social class (Delle Fave et al., 2011).

Flow research has been pursued since the 1970s, at first primarily in the laboratories of Csikszentmihalyi in the United States and Massimini in Italy (e.g., Csikszentmihalyi and Csikszentmihalyi, 1988; Inghilleri, 1999; Massimini and Carli, in Csikszentmihalyi and Csikszentmihalyi, 1988; Massimini and Delle Fave, 2000). Since then, researchers studying leisure (play, art, sport, games), intrinsic motivation, and interest have taken up the flow concept. Cultivating the flow experience has also drawn considerable interest from researchers and practitioners in schools and workplaces – that is, contexts where encouraging engagement is vitally important because of links to quality of life, learning, and development, as well as performance. Additionally, the flow concept has had an impact on professional sports, popular culture, and government, and it has been studied within positive psychology as a factor in well-being.

Table 1 The essential components of the flow state

Key dimensions of the flow state (Csikszentmihalyi, 1975/2000, 1990)	*Original descriptions from rock climbers (Csikszentmihalyi, 1975/2000)*
Total concentration on what one is doing; past, future, and stimuli outside of the immediate interaction recede	"It's a centering thing, being absolutely in the here and now, in the present" (p. 81)
A merging of action and awareness	"You're so involved in what you're doing [that] you aren't thinking about yourself as separate from the immediate activity. You're no longer a participant-observer, only a participant" (p. 86)
A sense of control; one feels that one will be able to respond to whatever occurs	"Once you're into the situation … you're very much in charge of it" (p. 81)
Loss of self-consciousness; one does not step outside of the stream of experience, watching and judging the self	"When you first start climbing you're very aware of your capabilities. But after a while you just do it without reflecting on it at the time" (p. 87)
Distorted sense of time; time may seem to dilate (slow down or stand still) or one may lose all track of time and later feel it passed very quickly	An "eternal moment" (p. 87)
'Autotelic' experience; the experience itself is intrinsically rewarding	"The purpose [of climbing is] not looking for a peak or utopia but staying in the flow …. you move up only to keep the flow going. There is no possible reason for climbing except the climbing itself" (pp. 47–48)

The Flow Model

The initial understanding of the nature and conditions of flow (Csikszentmihalyi, 1975/2000) was based on interviews with rock climbers, chess players, surgeons, and others pursuing activities thought to "maximize immediate, intrinsic rewards to the participant" (p. 21). In flow, the experience seamlessly unfolds from moment to moment and one enters a subjective state with the characteristics shown in **Table 1**. The central role of attention should be clear (for discussions of the dynamics of attention in flow, see Csikszentmihalyi and Csikszentmihalyi, 1988; Csikszentmihalyi and Nakamura, in Bruya, 2010).

In addition to these dimensions of the individual's subjective state, the initial research identified three proximal conditions conducive to entering flow. First, the flow state is more likely to occur when the person perceives *clear goals* along the way as the activity proceeds. Second, experiencing flow depends on perceiving *clear, immediate feedback* – unambiguous information about the progress being made and whether the course of action should be adjusted. Third, there needs to be a dynamic *balance between perceived opportunities for action (challenges) and perceived capacities for action (skills)*.

That is, a person operates at the limits of perceived capacities when in flow (cf deCharms, 1968; Deci, 1975; White, 1959). The state is one of dynamic equilibrium. Entering flow depends on establishing this balance (cf Berlyne's optimal arousal); staying in flow requires maintaining it. Importantly, the relation between perceived challenges and skills was employed in 1975 to sketch the broader experiential landscape associated with any potentially autotelic activity. Csikszentmihalyi (1975/2000) differentiated three conditions of experience in an activity: a flow channel along which perceived challenges and skills match at any level; a region of boredom, as opportunities for action relative to skills drop off; and a region of anxiety, as challenges increasingly exceed capacities for action.

Massimini and colleagues made important contributions in the 1980s to clarifying the role of challenges and skills in promoting flow. They observed that if operating at the limits of one's capacities is a condition for entering flow, then interactions perceived as offering few opportunities for action will not lead to experiencing flow even when one thinks that one has correspondingly little relevant skill. Employing the Experience Sampling Method (ESM) that had been developed by Csikszentmihalyi and colleagues to study daily life (see Section Measuring Flow), the Milan group thus began describing the flow condition as the balance of perceived challenges and skills specifically when both are above an individual's average levels (Massimini and Carli, in Csikszentmihalyi and Csikszentmihalyi, 1988). That is, flow is expected to occur when individuals perceive greater opportunities for action than they encounter on average, and they feel they have adequate skills to engage them. The research revealed a fourth subjective state, apathy, associated with low challenges and correspondingly low skills. Experientially, this is a state of stagnation and diffuse attention – the opposite of the flow state. In addition, the quality of experience when perceived skills exceed perceived challenges proved to be more positive than originally theorized.

The resolution of this phenomenological map can be made finer by differentiating the challenge/skill terrain into eight experiential channels rather than four quadrants (see **Figure 1**). Doing so reveals a gradient from flow to control to relaxation and then to boredom, as skills exceed challenges. Similarly it is possible to show empirically a gradient from flow to arousal and then to anxiety, as challenges exceed skills. Finally, the quality of experience (whether positive or negative) intensifies within a channel or quadrant as perceived challenges and skills move away from a person's average levels. Conceptual and methodological issues related to the role of perceived challenges and skills in flow continue to be active areas of theory and research. A key underlying distinction is between these conditions for entering flow and the subjective state itself (for summaries, see Delle Fave et al., 2011; Engeser, 2012).

Figure 1 Flow within the experiential landscape defined by a person's subjective challenges and skills, at two levels of resolution: the quadrant model (flow, relaxation, apathy, anxiety) and the 8-channel model (arousal, flow, control, etc.). Source: Massimini and Carli, 1988. In: Csikszentmihalyi, M., Csikszentmihalyi, I. (Eds.), Optimal Experience. Cambridge University Press, Cambridge.

Emergent Motivation, Learning, and Development

It should be evident that the view of human functioning associated with the flow model (see Inghilleri, 1999; Rathunde and Csikszentmihalyi, 2006) is consistent with active-organism, interactionist perspectives in psychology. It focuses on the dynamic system comprised of person and context, and the specific subjective states that are experienced in person–environment interactions. In two respects, the flow model describes motivation as arising out of these person–environment interactions; that is, as 'emergent motivation.'

First, in flow, what happens at any given moment is responsive to what happened the moment before within the interaction (Csikszentmihalyi, 1985), rather than being predetermined by characteristics of either the person (e.g., a drive) or the environment (e.g., a social role). Shifts in subjective state provide feedback about the person's changing relationship to the environment. In the unfolding interaction, a person may respond to experiencing anxiety or boredom by seeking to adjust their level of skill and/or challenge, in order to escape the aversive state and reenter flow. In this first sense, proximal goals may be emergent.

Second, flow experiences may lead to expansion or transformation of a person's goals and interests (Csikszentmihalyi and

Nakamura, 1999). That is, an individual may enter an activity by chance or in response to extrinsic demands rather than by choice, neither seeking nor embracing the opportunities for action it might hold. However, it is possible to come to experience the new or previously unengaging activity as intrinsically rewarding if the proximal conditions of the interaction lead the person to find flow in it. The motivation to persist in or return to the activity arises out of the absorbing experience itself. In this second sense, long-term goals or interests may be emergent.

The flow state is intrinsically rewarding; it encourages people to seek to repeat experiences in which they have previously found flow. However, the flow model suggests that as people master the challenges of an activity, they develop greater levels of skill and the activity ceases to be as involving as before. To keep experiencing flow, one must engage in increasingly complex challenges. This factor distinguishes the flow model from motivational theories that define optimal challenge in terms of either a homeostatic equilibrium point to be returned to, or a maximum level of challenge to be reached (Moneta and Csikszentmihalyi, 1996). The optimal level of challenge stretches existing skills, resulting in more complex capacities for action. Both in the moment and in the direction of a life, this introduces into psychological functioning a selective mechanism (Massimini and Delle Fave, 2000) that fosters development – the acquisition of skill within an existing activity and the identification of new paths to growth.

In the context of individual lives, a personal 'flow activity' is an activity of this kind, into which an individual selectively invests attention and energy because he or she has tended to find flow in it before (cf 'individual interests'). It provides the individual with opportunities for flow and skill growth, thereby contributing to the quality of life. Of course, one person's cherished flow activity may hold no appeal for another individual. In every society, however, pursuits have evolved that seem to comprise culturally provided affordances for optimal experience because they embody the conditions of flow so well. A sport or game is a paradigmatic example, presenting clearly defined goals, rules, feedback, and a set of graduated challenges. It helps focus the participant's attention by circumscribing the 'stimulus field' (Csikszentmihalyi, 1975/2000). This is a cultural flow activity. The individual–culture relationship mediated by flow is held to be reciprocal. When people selectively participate in the culture's flow activities, they are more likely to experience flow and the activities are more likely to persist in the culture (for fuller discussions, see Csikszentmihalyi and Massimini, 1985; Delle Fave et al., 2011; Inghilleri, 1999).

The Autotelic Personality

Selectively investing attention and energy in a specific flow activity is one way to experience flow more frequently. Another is through a general proneness to flow. While flow seems to be a virtually universal experience, there are marked differences in the frequency and intensity of individuals' experience of flow. A potential explanation for this relates to Csikszentmihalyi's (1975/2000) concept of the 'autotelic personality,' which suggests that some individuals are more prone to experiencing and staying in flow than others. Csikszentmihalyi defined the autotelic personality as someone who pursues activities for their own sake instead of an external goal. Autotelics have a low level of self-centeredness and neuroticism. The inherent sense of curiosity and interest that they have in the world leads them to seek opportunities where they can build their skills by testing them against sizable challenges, and their endurance and conscientiousness lead them to practice and persist (Baumann, 2012; Ullén et al., 2012). They are able to better manage the balance between challenges and skills that marks the flow experience. Those with autotelic personalities should possess 'metaskills' that allow them to not only enter and experience flow, but also maintain it for an extended period of time (Nakamura and Csikszentmihalyi, 2009).

Measuring Flow

Researchers have developed self-report and indirect methods of studying flow (see Nakamura and Csikszentmihalyi, 2009; Delle Fave et al., 2011). In-depth interviews have provided qualitative descriptions of the characteristics and conditions of flow, beginning with Csikszentmihalyi's (1975) study. Individual differences in the frequency of flow experiences and population incidence of different flow activities have been measured with survey items and the Flow Questionnaire. A number of validated scales measure either disposition to experience flow or situational (state) flow, either in one specific activity or in life more generally. The goal of studying the occurrence of situational flow across people's daily lives stimulated development of the ESM, which uses *in situ* reports of subjective experience at randomly sampled moments to anchor flow experiences in their real-life contexts. Currently, ESM researchers still operationalize both the flow state and flow conditions in multiple ways. In addition to these self-report methods, researchers more recently have developed experimental paradigms that induce flow in the laboratory through controlled manipulation of its theorized proximal conditions (e.g., the balance of challenges and skills provided by video games). There is growing interest in measuring flow's physiological correlates in and beyond the laboratory (see below). Some researchers have sought visible behavioral markers of the flow state. All these latter methods promise indirect rather than self-report measures of flow, holding out the possibility of studying flow experiences 'online' without disrupting their unfolding.

Measuring the autotelic personality has mainly focused on gathering ESM data and assessing how much time individuals spend in high-challenge, high-skill situations. Another strategy has been to measure how intrinsically motivated individuals are during high-challenge, high-skill activities. Non-ESM measures ask individuals how often they experience flow in general or tap underlying traits (see Baumann, 2012; Nakamura and Csikszentmihalyi, 2009; Ullén et al., 2012).

Flow in Work and Leisure

Cross-culturally, the two prominent contexts in which adults report experiencing flow are work and leisure. Leisure is mentioned more often by Western respondents and work by non-Western ones (Delle Fave et al., 2011).

Leisure

Leisure activities (i.e., how individuals spend free time outside of work) are often intrinsically motivating and, therefore, should produce flow if other conditions of the experience are met (Csikszentmihalyi and LeFevre, 1989). Leisure time can be devoted to a myriad of different activities, such as hobbies (e.g., gardening), sports, and video games. Based on ESM research, Csikszentmihalyi and others separate leisure activities into two categories: Active leisure and passive leisure. Passive leisure activities, such as watching television, do not require substantial energy and are generally relaxing (Csikszentmihalyi, 1990). Despite occupying large amounts of free time in some cultures, watching television and similar activities do not usually lead to flow and can decrease positive affect (Csikszentmihalyi and LeFevre, 1989; Kubey and Csikszentmihalyi, 2002).

Active leisure pursuits may be structured and require substantial concentration toward achieving a certain goal (see Delle Fave et al., 2011). They include serious leisure activities that allow individuals to develop long-term skills or knowledge (e.g., reading a book). As previously mentioned, the active leisure activities of sports and games often exemplify flow's proximal conditions, containing clear goals, unambiguous feedback, and high challenges. Flow is more likely to occur during active leisure activities when the perceived ability of individuals is high and, in turn, encourages them to pursue high-challenge situations (Perkins and Nakamura, 2013). High-skill players during video games experience greater levels of flow when engaged in high-challenge situations, and chess players who are more intrinsically motivated enjoy competing against more challenging opponents than players who are focused on winning (Abuhamdeh and Csikszentmihalyi, 2009).

Work

While the original conceptualization of flow mainly focused on leisure activities, the integral flow condition of balanced challenge and skill has been found to occur more often in the workplace (Csikszentmihalyi, 1990; Csikszentmihalyi and LeFevre, 1989). An ESM sample of managers, engineers, clerical workers, and blue-collar workers spent 54% of their time at work in high-challenge, high-skill situations compared to only 17% during leisure activities (Csikszentmihalyi and LeFevre, 1989). The frequent occurrence of flow in the workplace has been called a paradox; workers report feeling focused and creative at work but say that they would rather be engaged in leisure activities (Csikszentmihalyi, 1990). This may reflect cultural attitudes toward work versus leisure or the stress and strain that accompanies flow at work (Nakamura and Csikszentmihalyi, 2009). In either case, it is a testament to the multidimensionality of the flow experience and the challenges researchers have in measuring it: While workers may often encounter high-skill, high-challenge situations at work, this alone may not capture whether they are experiencing the flow state. A more in-depth examination of flow at work illuminates why the experience often occurs in this setting. Flow at work is defined as short-term peak experiences where an individual is completely engaged, absorbed, and enjoys the task at hand. Many jobs have built-in characteristics that would be conducive to experiencing flow, specifically clear goals, immediate feedback, and high-challenge tasks (Csikszentmihalyi, 1990; Fullagar and Kelloway, 2013).

What Facilitates Flow at Work?

Skill variety and autonomy are two job characteristics that predict flow (see Fullagar and Kelloway, 2013). Research also shows both personal resources (e.g., self-efficacy) and organizational resources (e.g., social support, innovation, and clear goals) increase flow's occurrence in the workplace (Salanova et al., 2006; Fullagar and Kelloway, 2013). Flow at work is associated with subjective well-being (see Fullagar and Kelloway, 2013), and the relationship between flow and organizational performance has been found to be partially mediated by positive mood (Eisenberger et al., 2005).

To summarize the research investigating flow in the context of work and leisure, individuals are more likely to encounter high-challenge, high-skill situations at work than during leisure time, which may indicate that individuals are not spending their leisure time in a flow-conducive manner. Work is often stressful and exhausting for individuals, which may increase the appeal of pursuing passive leisure activities. More research needs to be done to discover why individuals are not more inclined to pursue active leisure activities in which they find flow. Furthermore, it is essential that researchers understand the full scope of flow's occurrence in the workplace since high-challenge, high-skill situations may not be a sufficient condition for flow in this context due to the stresses and extrinsic rewards that work holds.

The Potential for OverFlow

Although flow has mainly been associated with positive outcomes, it is important to acknowledge its potentially negative effects (see Schüler, 2012). Several of flow's characteristics, specifically deep concentration, time distortion, and a sense of control, can impede individuals from living a balanced life, due to single-minded devotion to one activity.

Flow activities are not necessarily health-promoting. The intrinsic rewards that flow provides can cause individuals to become addicted to certain flow activities. Flow has been associated with exercise addiction, online game addiction, and Internet addiction. Indeed, flow is amoral. Thus, another potential dark side of the flow experience is that individuals could potentially enter flow through harmful – for example, aggressive or violent – behavior. For example, soldiers have reported having optimal experiences while killing others in the heat of combat.

Flow also can lead to risky behaviors, as some individuals constantly seek greater challenges as their skills improve to maintain the challenge–skill equilibrium that allows them to experience flow. This can result in risky behaviors (e.g., climbing a treacherous mountain with minimal support) when novice flow-seekers misread performance feedback and do not recognize their vulnerabilities.

Future Directions

Multiple emerging areas of flow research have the potential to substantially expand the overall understanding of the flow experience. This section focuses on several of the most burgeoning, rich areas of new flow research.

Social Flow

As individual flow experience becomes better understood, a new topic of flow research has begun to emerge: flow in social contexts, including dyads, groups, and teams. Walker (2010) has identified three types of flow experiences: Individual solitary flow (e.g., playing the guitar), coactive social flow (e.g., going on a jog with friends), and interactive social flow (e.g., playing on a basketball team). At least for college students, flow in both social contexts (coactive social flow and interactive social flow) was more enjoyable than individual flow. However, many questions remain, such as whether social flow is a distinct construct from individual flow, and how best to specifically assess social flow.

Along these lines, the presence of flow in the context of interpersonal relationships needs further examination. Pursuing close connections with others is one of the core motivations of human existence, and close relationships are associated with happiness and life satisfaction. Although close relationships would seemingly result in optimal experiences, little is known about the specific role that flow plays in romantic and other relationships.

The Psychophysiology of Flow

Another emerging topic of research is the psychophysiology of the flow experience. A pioneer in this area, Jean Hamilton, conducted a positron emission tomography study in 1984. Consistent with the view that concentration is effortless in flow (Csikszentmihalyi, 1975/2000, 1990), she found that the more autotelic individuals took less effort to regulate their attention on a laboratory task.

Two decades elapsed before theoretical work on the neuroscience of flow and effortless attention resumed (for a summary, see Delle Fave et al., 2011), with Dietrich and Weber producing conflicting theorizations regarding the role of the prefrontal cortex (the brain region associated with higher cognition). While Dietrich suggested that there is a transient decrease of neural activity in the prefrontal cortex during flow (allowing the fluent execution of highly practiced skill), Weber and colleagues objected that prefrontal activity has been shown to increase in focused attention and that flow has a different neural basis: synchronization of the brain's attentional and reward networks.

Empirical research on the brain basis of flow and its correlates is germinal (for a recent summary, see Peifer, 2012). Both Keller and colleagues and Peifer have reported an inverted-U relationship between flow and markers of effort (lowered heart rate variability, cortisol). Also of note, Ullén and colleagues (in Bruya, 2010) hypothesized that effortless attention is associated with the *interaction* of high attention and positive affect and found that the physiological correlates of both (sympathetic autonomic nervous system activation, deep breathing, and activation of the 'smile' muscle) characterized pianists in flow. Firm claims about the psychophysiological correlates of flow have yet to be established but this is an active research front warranting further investigation.

Applications of the Flow Concept

As flow research continues to flourish, determining the most effective applications of the theory should be a priority. Flow interventions can either design activities and environments so they are conducive to experiencing flow, or they can directly help individuals enter a flow state (Nakamura and Csikszentmihalyi, 2009). Several flow interventions have been implemented with considerable success, including Green Cargo (a Swedish state-owned transportation company) implementing practices based on flow principles to help the company become profitable for the first time in 115 years. Flow principles also informed exhibit design at Los Angeles' Getty Museum and product design at Nissan USA (Nakamura and Csikszentmihalyi, 2009).

The flow model has also been applied in the educational context. Research shows that learning is often a flow experience but schooling too often is not. The practices of effective schools and programs have been studied from a flow perspective and programs that are directly based on the flow model have been implemented in some private and public educational settings. For example, the Key School, an Indianapolis public school, developed a Flow Activities Center, which gives students regular opportunities to identify personal flow activities by choosing what activities they would like to pursue. For reviews of educational applications, as well as the underlying research on the flow–performance relationship and on differences in student flow experience by school type, subject matter, and pedagogy, see Delle Fave et al. (2011) and Shernoff and Csikszentmihalyi (2011). More work is needed to understand the antecedents and consequences of flow in the classroom in order to design empirically based interventions that benefit both teachers and students.

Conclusion

As demonstrated by the growing body of research investigating the flow experience, flow is a theory with broad relevance. Flow plays a significant role in personal, organizational, and social contexts, and current research continues to expand flow's range of application. In recent years, the flow experience has been situated as a key theory within the field of positive psychology, which goes beyond human deficits to focus on how individuals, organizations, and communities flourish and thrive. In addition to its contribution to motivational psychology, the concept of flow has played an integral role in positive psychology's mission of understanding how individuals can lead happier, more fulfilling lives.

Abstract

Stuttering is a global, pancultural disturbance that has afflicted human beings throughout time. An increasing corpus of research has identified the role of genetics, physiology, and aberrant neuromotor control in the genesis of this disorder. Further, evolving animal models of stuttering (e.g., birdsong) and aspects of 'acquired stuttering' lend information to understanding stuttering. Hopefully, the expansion of these multiple research venues will identify the causation and possible cure for this disorder.

Stuttering is a global, pancultural disturbance of speech that has been with us throughout time. Individuals who have stuttered since childhood are sometimes referred to as developmental stutterers (DS) and persons who stutter (PWS). These individuals represent over 1% of the adult population (Porfert and Rosenfield, 1978) and endure considerable emotional pain and social stigma, as well as compromise in the marketplace and workforce. Heretofore fluent adult individuals rendered dysfluent by neurogenic compromise are referred to as acquired stutterers (AS) and have speech-motor characteristics different from DS.

There are multiple ancient references to stuttering, including ancient Mesopotamian clay tablets, Egyptian hieroglyphics ('nit-nit'), the Old Testament (Moses stuttered), and the Holy Koran. Recent scientific investigations of dysfluent speech-motor output substantiate organic factors in the etiology of stuttering and highlight stuttering as a window into understanding normal as well as abnormal production of speech-motor control.

Definition

Bloodstein and Bernstein-Ratner (2007) review the multiple definitions of stuttering. The definition of stuttering significantly alters clinical as well as research paradigms. What is a 'stutter'? If a child bounces on a sound, or someone repeats a whole word, is that a stuttered dysfluency? Are they equivalent in etiology and in genesis? Should investigators consider dysfluency in adult stutterers to be isomorphic to effortless dysfluency (e.g., 'normal fluency of childhood') seen frequently among children? Answers to these questions significantly impact our inquiries into the etiology of dysfluency.

Children who stutter (DS) have difficulty producing intended words and sounds. They know what they want to say but are unable to do so. Thus, their language is normal but their speech is not. Further, the location of stuttered dysfluencies in DS is not random. These are often located at the beginning of sentences and phrases and are associated with part-word repetitions, as opposed to repetition of whole words or phrases. Sometimes, the child will back up in producing the sentence and repeat whole phrases or portions of words in an effort to overcome the dysfluent output. Regardless, the core problem of dysfluency remains repetition of a single sound or a fragment of a word (Bloodstein and Bernstein-Ratner, 2007).

In an effort to achieve fluent production and overcome these dysfluencies, the stuttering child often employs circumlocutions, substituting one word for the other. Thus, a child who stutters, might say "g-g-g … see you later," instead of continuing to stutter on the /g/ of 'good-bye.' Acoustic analysis suggests when that child attempts to say "g-g-good-bye," the initial /g/ sound in the stuttered dysfluency acoustically differs from his final, fluently produced target word. This is in addition to what are identified as 'secondary characteristics' of stuttering, referring to facial distortions associated with the speaker's effort to force out the appropriate sound. Whatever stuttering behavior one produces, that behavior reflects the underlying difficulty producing the sound, with a superimposed maneuver to achieve fluent speech (Bloodstein, 2008; Rosenfield, 2001).

It is not a simple task to identify the locus of dysfluency. If a stutterer says "s-s-sound," where is the actual dysfluency? Many investigators previously maintained that the dysfluency was on the /s/, but now most would contend the deficit is on the *transition* from one sound to the next. The stutterer is able to say the /s/ but not the /*ound*/. The stutterer's strategy to achieve fluent output can result in repeating the /s/ until the transition into the ensuing /*ound*/ is secured (Rosenfield, 1997, 2001).

Clinical Features of Stuttering

As previously noted, stuttered dysfluencies are not randomly located within a sentence. Instead, they occur where fluent speakers' occasional dysfluencies also occur – at the beginning of sentences and phrases. Thus, one seldom hears a stutterer say, "Go to the building-g-g-g." Rather, a stutterer says "G-g-go to the building" (Bloodstein and Bernstein-Ratner, 2007; **Figure 1**).

Emotional stress can make stuttering worse, but is not the cause of stuttering. A 10-year-old stutterer may be nervous regarding presenting a book report in front of his class due to fear of embarrassment due to stuttering, yet is fluent when singing before the class despite emotional angst regarding singing in front of others. The fact that emotional stress

Figure 1 This is a spectrogram of a stutterer saying, 'domestic.' He repeats the /d/ sound several times before fluently achieving the target word, 'domestic' (spectrogram of stuttered speech).

exacerbates stuttering is consistent with stuttering being a disturbance of neuromotor control. Motor systems are affect-sensitive systems and worsen with stress.

Stutterers seldom repeat whole words. Their dysfluent output usually contains word fragments. The sounds (fragments, part-words) differ from the target sounds the stutterers are trying fluently to produce (Bloodstein and Bernstein-Ratner, 2007; Rosenfield, 1997, 2001).

Several speech-related maneuvers increase fluent output in stutterers, the most potent of which is singing. Stutterers' speech also considerably improves with choral reading, speaking in cadence with a metronome, or when loud, broadband noise prohibits their hearing their own speech. Delayed auditory feedback improves stuttering, as does speaking during inhalation, or repeating the same passage (adaptation effect) (Bloodstein, 2008).

Genetics

Stuttering is not randomly dispersed between males and females. Stuttering is significantly more prevalent among males than females. Eighty percent of children 'outgrow' their stutter but 20% do not. This confounding variable necessitates the importance of identifying current stutterers as well as past stutterers in any investigation of genetic causation of stuttering.

Genetic investigations among twins who stutter often focus upon concordance rates among monozygotic versus dizygotic twin pairs, as well as analyses of pedigrees in different families. Many of these investigations are hampered by small sample size, difficulty ascertaining twin status, and difficulty assessing who has what type of speech disruption. Howie (1981)directly examined twin pairs of stutterers, noting that 63% of 16 monozygotic twin pairs and 19% of 13 dizygotic twin pairs were concordant for stuttering. Andrews et al. (1991) investigated 3800 twins through self-employed reporting and ascertained 20% concordance among 50 monozygotic twin pairs, and 3% concordance among 85 dizygotic twin pairs. These investigations suggest heredity is an important factor in the genesis of stuttering, but may not be a sufficient condition, since the concordance among homozygous (identical, same genetic code) twins was not 100%. Therefore, environmental factors may also be a factor in the causation of stuttering.

Other investigators analyzed aggregates of stuttering within families, rather than primarily focusing upon twin pairs. Their findings suggest relatives of PWS have an increased risk of stuttering, ranging from a 3- to 10-fold increase. Segregation patterns of stuttering in these families do not suggest a single-gene, fully penetrable transmission model of inheritance, such as autosomal dominant, autosomal recessive, or X-linked. Rather, these studies suggest a diallelic model, with penetrance affected by whether a parent stutters and the sex of that parent who stutterers (higher among male-stuttering parents) (Kang et al., 2010; Viswanath et al., 2004; Suresh et al., 2006).

There is no singular genetic marker for people who stutter. Genetic predisposition may be a necessary condition for people to stutter, but this predisposition may not be sufficient. Similarly, investigations employing multiple avenues of brain imaging fail to identify a singular brain-related abnormality in people who stutter, despite several investigators identifying multiple cerebral (and cerebral-related) differences between those who stutter and their fluent counterparts.

Brain Imaging

There are many obfuscating factors in studying brain imaging in people who stutter, What is a stutter and how does one ascertain the severity of a stuttered dysfluency? For instance, is "b-b-b-ook" more severely dysfluent when repeating the 'b' 10 times, since both represent difficulty in achieving production of the correct sound? The repetition of the 'b' can merely represent accommodating to the 'error' in the speech-motor control system and not be isomorphic with the error itself. Is struggling with the sound once and then changing the word to a more fluently produced word, such as 'text,' a similar deficit? How should investigators incorporate previously directly or indirectly learned therapeutic strategies that ameliorate the stuttered output? Should people who stutter be evaluated in

groups and, if so, how should the groups be composed? Should individual stutterers, as opposed to groups of stutterers, be studied in the same paradigm in different trials and on different days? How does one incorporate strong handedness with less strong handedness, since handedness is a marker of language cerebral laterality and language laterality has been queried as a causal factor in stuttering? When one has stuttered for years, how does the investigator know which results relate to the stuttering itself or to the accommodation over years to the stuttering deficit, or even to the therapy itself (Rosenfield, 2001; Bloodstein and Bernstein-Ratner, 2007; Rosenfield, 2012)? Most investigators are cognizant of these constraints, as their ongoing research employs varying analyses of different brain imaging paradigms.

Sommer et al. (2002) employed diffusion tensor imaging (DTI) of the brain, a technique which assesses white matter neural fibers. These researchers observed that stutterers had fewer white matter fibers in the left brain, immediately below the representation of the tongue and laryngeal areas, and queried disconnection between the representation of the oropharynx (Brodmann's area 43) within sensorimotor cortex. Other investigators found DTI white matter abnormalities in the superior longitudinal fasciculus and corpus callosum (Chang et al., 2011; Cykowski et al., 2010). Still others, using different brain imaging paradigms, observed increased activations in the anterior insula, premotor cortex, and cerebellum, with decreased activation in superior temporal cortex (Brown et al., 2005; Ingham et al., 2012).

Other studies assess cerebral volumetric differences between stutterers and nonstutterers, as opposed to brain imaging assessment of cerebral physiological function or structural deficits. Foundas et al. (2001) observed that stutterers had qualitative differences in frontal lobe gyral patterns involving Broca's area and quantitative differences in the posterior temporal lobe regions, involving Wernicke's area. Given that most right-handed fluent speakers have a larger left superior posterior temporal area (Brodmann's area 22, planum temporale), primarily consisting of Wernicke's area, their most salient finding was that Wernicke's area on the left and its corresponding area on the right were bilaterally larger but less asymmetric in stutterers than in normal speakers.

Foundas et al. (2001) hypothesized that these brain abnormalities permit normal development of language but later contribute to abnormalities in the motor output of language, primarily speech. They query whether perisylvian (including Broca's and Wernicke's areas) speech–language cortex compromise contributes to instability in interaction between an outer 'linguistic' loop and an inner 'phonatory' loop, resulting in stuttering (discussed below in greater detail; Nudelman et al., 1992; Anderson et al., 1999). They note that abnormalities in the anatomic substrates of language can be different among stutterers, some having difficulty processing of speech-motor control due to aberrancies in frontal opercular areas, others having compromise near Wernicke's Area.

Other investigators employ PET and fMRI experiments in stuttering. PET experiments, including reading aloud, reading silently, and choral reading, suggest different activation patterns in stutterers versus nonstutterers (Fox et al., 1996; Braun et al., 1997; DeNil et al., 2000). Despite differences in experimental design, these studies highlight that right-handed stutterers lateralize activations to the right hemisphere in contrast to fluent speakers, who lateralize activations to the left hemisphere. Fox et al. (1996) observed that stuttering during solo reading induced widespread activation of motor systems in both the cerebrum and the cerebellum, with a right dominance.

Consistent with this finding, Braun et al. (1997) noted in stutterers that regional responses were absent, bilateral, or lateralized to the right hemisphere when the PWS engaged in speech production during stuttering episodes. DeNil et al. (2000) support this conclusion by observing a proportionately greater right hemisphere activation in stutterers reading individual words overtly or covertly in contrast to proportionately greater activation in the left hemisphere in nonstutterer controls. Fox et al. (1996) and Braun et al. (1997) conclude similar results pertaining to fluency evoked by chorus reading and evoked by prolongation of speech sounds. These studies suggest that brain activation patterns of stutterers differ from that of nonstutterers, not only during stuttered speech but also when PWS produce speech fluently.

Some scientists attempt to combine the excellent spatial resolution capability of fMRI with the excellent temporal resolution of magnetoencephalography (MEG), a technique permitting investigation of timing of cortical activation sequences in various tasks. MEG provides superb temporal resolution with good accuracy of localization of active cortical areas, and is useful for characterizing activation sequence from visual perception to oral output and for identifying cortical correlates of disorders of these processes. Salmelin et al. (2000) studied MEG paradigms in PWS and fluent controls. He had both groups read isolated nouns aloud in a delayed reading paradigm. The stutterers were fairly fluent in this task. Despite similar overt performance between the two groups, the cortical evoked patterns revealed clear differences, both in the evoked responses, time-locked to word presentation and mouth movement onset, and in task-related suppression of 20-Hz oscillations. Within the first 400 ms after seeing the word, physiologic processing in fluent speakers advanced from the left inferior frontal cortex (articulatory programming) to the left lateral central sulcus and dorsal premotor cortex (motor preparation). This sequence was reversed in stutterers; they had early left motor cortex activation followed by delayed left inferior frontal signals. Stutterers seem to initiate motor programming prior to preparation of the articulatory code. Suppression of motor cortical 20-Hz rhythms, caused by neuronal-related processing of tasks, occurred bilaterally in stutterers and fluent speakers, but the suppression was dominant in the right hemisphere in the stutterers whereas it was dominant in the left hemisphere in fluent speakers. Accordingly, the right frontal cortex was very active during speech in DS but did not generate synchronous time-locked responses. The authors postulate a dysfunctional network of the left inferior frontal cortex and right motor/premotor cortex network in stutterers.

Theories of Stuttering

Regardless of genetic or brain imaging input pertaining to why people stutter, or what definition of stuttering one chooses,

stutterers have difficulty controlling their laryngeal sound source and concurrent articulation. Investigators have demonstrated adductor as well as the abductor laryngeal muscles co-contract during dysfluencies, making it impossible to produce normal speech output. When stutterers try to 'fake' these dysfluencies, or if fluent speakers try to produce these, they do not produce these co-contractions. Electromyographic relationships between laryngeal abductor and adductor muscles are abnormal during moments of the stutterer's dysfluency (reviewed in Bloodstein and Bernstein-Ratner, 2007). Further, studies demonstrate that stutterers with laryngeal cancer who subsequently underwent laryngectomy and spoke with an electronic voicer, all became totally fluent with the electronic voicing apparatus (Rosenfield and Freeman, 1983).

Some theories contend aberrant cerebral laterality of language causes stuttering. Within this context, these focus on handedness and correlated cerebral laterality as a cause for stuttering, since right-handedness reflects left cerebral hemisphere laterality for language, and left-handedness reflects mixed or right cerebral hemisphere laterality for language. Investigations exploring cerebral hemisphere laterality for language evaluate handedness, dichotic listening (e.g., competing binaural linguistic inputs to measure laterality), and visual stimuli to competing hemispheres, all making this theory enticing.

Investigations of dichotic listening suggest PWS have disrupted auditory processing, compromising meaningful linguistic stimuli; many stutterers lack the normal left brain (i.e., right ear) advantage (Rosenfield and Goodglass, 1980; reviewed in Bloodstein and Bernstein-Ratner, 2007). However, being left- or right-handed has never been demonstrated to be a necessary or sufficient condition for stuttering (reviewed in Rosenfield, 1997; in Bloodstein and Bernstein-Ratner, 2007).

Some maintain that stuttering relates to abnormal auditory self-monitoring of speech. When loud, broadband noise prohibits a stutterer from hearing his speech, fluency markedly improves. This has also been observed with delayed auditory feedback, a setting in which a stutterer hears what he says 250 ms after he speaks. Frequency-altered feedback, in which the PWS hears what he/she just spoke but with an altered frequency, also promotes fluency (Kalinowski et al., 1993).

Other investigators contend stuttering reflects periodic irregularities in timing of muscle movements within the speech-motor control system (Zimmermann, 1980). When background muscle tension is elevated, as it can be in DS (Freeman and Ushijima, 1978), the high-precision adjustments needed to produce normal speech output are difficult to perform, and speech-motor movements are not smooth. Not only do stutterers have poor coordination of antagonist laryngeal muscles (Freeman and Ushijima, 1978) but also they are systematically slower in initiating phonation than are fluent speakers (Bloodstein and Bernstein-Ratner, 2007). Caruso (1991) adds that the supplementary motor area is dysfunctional in stuttering, resulting in poor motor planning of the speech output.

The above theories primarily note differences between groups of stutterers and groups of nonstutterers, positing mechanisms not common to all the PWS, since some of the PWS do not have the abnormalities noted. One theory, which has gained some popularity, describes the necessary and sufficient conditions for a dysfluency to occur. It is complex, involves mathematical modeling, and also incorporates control theory. Below, we present a basic discussion of control theory and its subsequent modeling of the necessary and sufficient conditions for stuttered dysfluencies to occur.

Employing control theory, researchers (Nudelman et al., 1989; Rosenfield et al., 1991; Anderson et al., 1999; Foundas et al., 2001) model the speech-motor control system as consisting of two nested loops, an inner phonatory loop producing sound and an outer linguistic loop that selects the sounds to be produced. Stuttering occurs when the timing between these 'functional loops' is disrupted. Evidence suggests that stutterers have temporal slowing within the outer loop. Some data (Anderson et al., 1999; Foundas et al., 2001) suggest that perisylvian speech–language cortex mediates the outer loop, whereas corticostriatal–thalamocortical circuits mediate the inner loop. Anderson et al. (1999) further corroborate this hypothesis by noting that dopamine blockade and Parkinson disease slow the inner cortical–basal ganglia loop, reducing the dysfluency in PWS.

Some investigators believe altered sensory (auditory) feedback in PWS causes unstable/dysfluent speech (reviewed in Civier et al., 2010). Others subscribe to the 'covert repair hypothesis' (Postma and Kolk, 1993), positing PWS make errors in phonological planning, erroneously formulated prior to the articulation of sound, resulting in the internal self-monitoring system stopping speech output. Others (e.g., Howell, 2004) suggest lack of readiness itself in the motor plan. Stromsta (1986) believes stuttering results from insufficient coarticulation – the PWS fails the preparatory planning of articulation, resulting in the articulators not being correctly positioned to proceed, causing halting of speech. Peters et al. (2000) propose the nexus of stuttering lies within the lower processing stages of the speech process, involving abnormal parameter settings for muscular force and muscular command execution.

Modeling of any disease is facilitated with an animal model of that disease. Our laboratory has developed an animal model of stuttering, hoping to delineate the neurophysiology and neuropharmacology underlying fluent and dysfluent production of birdsong (Helekar et al., 2000, 2003; Rosenfield et al., 2001; Helekar et al., 2013), possibly relating that to the aberrant speech in PWS.

Animal Modeling of Stuttering

Human beings have a unique system of language, whereas nonhuman animals have a system of communication. Animals can signal danger or food to another animal, but are not capable of producing rich language akin to ours, which incorporates semantics, phonology and, especially, a generative grammar. However, some nonhuman species do share with us mechanisms of sound production. For instance, zebra finches (*Taenopygia guttata*) have many features pertaining to communication and sound production similar to humans. Both zebra finches and human beings have critical periods during development during which they must hear the sounds of their respective communication/language they are to produce, and there are specific periods during which they must hear these sounds and practice them. For instance, a zebra

Figure 2 Spectograms of normal Zebra finch birdsong. The horizontal axis again reflects time; vertical axis reflects frequencies. Note that the Zebra finch birdsong is spectrally complex and changes over time, sharing these properties with humans (normal birdsong).

finch must hear songs from its adult tutors by day 65 and practice it by day 90. If disruption in hearing or social isolation prohibits this time course, the bird will not learn normal adult birdsong. Similarly, young children must hear and practice sounds they are to make if they are to acquire the language of their parents.

Zebra finches and humans have a spectrally and temporally diverse sound output (i.e., multiple frequencies and changes in frequencies over time). Both the finches and humans have brains that control these sound outputs and both have an established hierarchy (Rosenfield et al., 2001; Helekar et al., 2000, 2003, 2013).

Our laboratory has demonstrated that ~5% of Zebra finches born to normal parents and raised among normal birds producing normal birdsong have phonatory iterations similar to stuttering. When these birds raise other birds, born to normals, ~60% of these birds stutter. However, although the latter have multiple phonatory iterations, they do not repeat the spectral content of the birds from which they learned to stutter. In other words, they learn to make an error in timing,

Figure 3 These spectograms describe phonatory iterations in a bird. Note the repetition of the 'syllable' at the end of the motif (stuttering in birds).

but not in the frequency domain. They have considerable improvement in these abnormal repetitions when they are placed in isolation or among normal singers (reviewed in Rosenfield et al., 2001; Helekar et al., 2013).

Thus, there appears to be a 'rule to repeat' in birdsong. Some birds (~5%) are born repeaters, perhaps reflecting a genetic mandate. Others birds learn to repeat abnormally and can improve toward normalcy with time, but still have the stuttering (reviewed in Rosenfield et al., 2001; Helekar et al., 2013).

Zebra finches provide a good animal model of stuttering. Similar to human stutterers, the birds' stuttering is position-specific, although it is at the end of the motif (e.g., major division of song production), whereas humans stutter at the beginning of sentences and phrases (see **Figures 2** and **3**).

The birds' and humans' errors are repetitive and nonvoluntary, as suggested by the regularity of the iterations (Helekar et al., 2013). One presumes the birds, similar to humans, prefer not to stutter, given that the tutored repeaters improve

Table 1 Acquired stuttering

	Developmental stuttering	*Acquired stuttering*	*Cluttering*
Locus of lesion	Unknown	Usually cortical, but can be subcortical	Unknown
Cause	Unknown	Vascular, metabolic, tumor	Unknown
Duration	80% of children outgrow: Adults have a worse prognosis	Unilateral: Good prognosis Bilateral: Poor prognosis	Varies
Locus of dysfluency	Beginning of sentence or phrase	Frequently scattered throughout sentence	Varies
Singing	Fluent	May improve somewhat, but not totally fluent	Varies
Onset	Subacute	Subacute or acute	Gradual
Reaction to dysfluencies	Anxious	Not anxious	Usually not concerned

significantly when they are placed among normal singing adults (Helekar et al., 2013). It is not known whether the birds that stutter are distraught by their abnormal iterations or whether their colleagues perceive them as different.

If one disregards the abstract linguistic and cognitive elements of speech and focuses, instead, on vocal motor components, songbird vocalization provides substantial insight into human speech-motor control disorders. Similarities between birdsong and speech can help understand the pathophysiology of human dysfluencies, and possibly in testing neuromotor theories of stuttering.

Acquired Stuttering

Acquired stuttering (AS) was initially reported by Rosenfield in 1972 and in ensuing years has been substantiated by many other investigators. As noted in that report, AS differs from DS in that the former is dysfluent throughout the sentence, stutters when singing, and is oftentimes not emotionally disturbed by their dysfluency. AS can be caused by cerebral injury, involving either hemisphere and multiple locations. The injury is usually mild. Prognosis is good if the compromise is unilateral but less so if brain damage is bilateral. In some AS patients, there may be psychogenic factors (Rosenfield and Barroso, 2000).

Whereas DS have difficulty achieving the target sound (e.g., ba-ba-ba-book), the AS achieves the target sound, repeating that sound (e.g., boo-boo-book). This difference is often clinically perceptible at the bedside.

Cluttering is sometimes confused with stuttering. Clutterers produce abnormal speech, characterized by excessive speed, repetition, interjections, drawling, disturbed prosody (i.e., altered rhythm of speech), and monotonous sound. Sometimes, these patients have inconsistent articulatory disturbances. Some investigators contend clutterers also make many grammatical errors, are hyperactive, have compromised concentration and poorly integrated thought processes.

Many clutterers omit sounds, syllables, and whole words, and invert the orders of sound, repeat the initial sound, and prolong several syllables of the word. Their rate of speech is usually very rapid, and the listener often complains about the rapidity of the speech. Opposed to DS, clutterers frequently are not concerned regarding their speech deficits (see **Table 1**; Rosenfield and Barroso, 2000; Bloodstein and Bernstein-Ratner, 2007).

Conclusion

Stuttering is a complex disturbance reflecting abnormal cerebral neuromotor processing of speech-related signals. There is probably a strong genetic component to stuttering, based at a minimum on studies of twin pairs and the marked prevalence of stuttering among males, but a genetic predisposition may not be sufficient to cause stuttering. Current investigations, employing clinical as well as genetic and brain imaging studies, coupled with studies in animals, may provide more insight into this pancultural, global disturbance.

Focus Groups

Martha Ann Carey, Kells Consulting, Media, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Focus groups are popular in social science research as well as in marketing and other business areas. When participants feel comfortable and the group facilitator is well prepared, the conversation usually leads to rich stories that probably would not be told in such detail in another type of setting. This technique can be very engaging for participants, especially persons from communities who often do not have a voice in matters that affect them. Focus groups are best suited to environments and groups where the members are knowledgeable, willing, and capable of communicating; the topic and the group setting are compatible with group interaction; and the group facilitator has adequate skills.

This article presents the basics of this technique so as to assist in the understanding of the character of focus groups and their potentials. For additional information and examples of the needed documents (invitation letter, introduction to the session, guideline questions, checklist, format for reporting), please see Carey and Asbury (2012) and Krueger and Casey (2009).

Definition and Development

The definitions of a focus group vary but usually include a semi-structured session with multiple participants, an informal setting, moderation by a facilitator and often a co-facilitator, the use of general guideline questions and/or other data elicitation stimuli such as photos, and a means to record the information generated through group interactions (Carey and Asbury, 2012; Krueger and Casey, 2009). Basically, focus groups are a data collection technique that combines principles of qualitative research and knowledge of small group dynamics. This approach capitalizes on the interaction among the group members to enhance the collection of deep, strongly held beliefs and perspectives. This approach, as well as most qualitative methods, is especially useful to explore new topics and to examine complex issues involving values and beliefs that underlie behavior. Some sessions may provide helpful social support and education, but this is not the goal of the focus group. Focus group sessions generally consist of a one-time meeting of persons who have a common experience, such as a new diagnosis of cancer or experience as a caregiver for an elderly spouse.

The development of this approach is generally associated with the research programs of Paul Lazarsfeld, Robert Merton, and colleagues (Merton et al., 1990). Marketing studies have extensively used this approach, and politicians use focus group data to help shape their campaigns. Education, nursing, psychology, social work, and sociology are increasingly using focus groups in programs of research.

Similar to other qualitative techniques, focus groups are not useful when the researcher needs to assess the magnitude of a problem. Also, when rapport and trust cannot be established in the group setting, the data will be too comprised to be of value. Trust involves both the group members and the world outside of the session, and it can be affected by ongoing relationships among members of the group. Other issues may arise due to the sensitive nature of the topic, vulnerability of the population, and concerns with the confidentiality of the data. In some instances, a taboo subject may be better explored in an individual interview or via a computer interview than in a group setting. However, there is some evidence that groups may facilitate the discussion of sensitive topics (Kvale and Brinkmann, 2009).

Virtual Focus Groups

Researchers increasingly are exploring the potential of using telephone, the Internet, and computer-mediated approaches. Possible advantages include access to participants at a distance, access to persons who may be reluctant to join a face-to-face meeting due to physical problems, reduced cost of arranging sessions, potentially increased disclosure due to perceived anonymity, and more open responses (this varies with topic and population). Asynchronous online methods allow participants to engage at their convenience and their own pace.

Disadvantages for online sessions may include limited depth of comments, limited opportunity for the facilitator to guide and follow up on questions, a potential of online exploitation particularly for young participants, more complex issues of data security, and a possible misunderstanding of comments due to absence of nonverbal cues to assist in understanding comments. Also, it is generally harder to establish trust and rapport, and having to type thoughts is a more demanding task than speaking and may lead to a reduction in participation. In a synchronous session, a delay between responses may lead to less interaction and less synergy. Technology may, but not necessarily will, somewhat limit free communication. Abbreviations of emotion using punctuation symbols can help somewhat in interpreting text. Compared to online focus groups, phone-based focus groups have fewer disadvantages due to the perception of increased social cohesion because participants are able to use information from the characteristics (e.g., intonation, pacing) of actual voices.

In general, data collection may be somewhat constrained by the online type of medium; group interaction will be less and data will be less rich and deep. Adaptations could be made to enhance group interaction such as small size, previous contact

to establish rapport, and extra effort to describe the study and how data will be stored. However, a sensitive or moderately sensitive topic may be more openly discussed online due to a possible comfort level resulting from some degree of anonymity. If the study's purpose can be met, this approach could be preferred.

Mixed-Integrated Methods

Focus groups, as well as other qualitative approaches, have often been used to identify and explore the major concerns in a topic that is new or not well understood. The natural vocabulary of participants can be used in the development of items for a questionnaire. In addition, when planning to use a well-established questionnaire in a population different from the population where it was developed, the meaning of items can be explored in a focus group. Planning and research design can balance the strengths and weaknesses of each of the qualitative and quantitative approaches. Qualitative approaches have been used in combination with quantitative approaches in sequence or concurrently to reinforce, explain, or expand the data. To help explain quantitative results, focus groups have been used to understand the unanticipated or unexpected results of quantitative studies when the psychosocial instruments were used with a new population (Carey and Smith, 1992). Qualitative methods have also been used to explore the processes that underlie quantitative outcomes.

Criticisms

Criticisms common to many qualitative studies include the limited representativeness of samples, questionable validity of results, limited generalizability, lack of synthesis or under-analyzed findings, and inadequate documentation of processes. Concerns unique to focus group include data quality, analysis, and ethics. Data quality will be limited if the session is dominated by one or two people. When this occurs, it usually involves variation in power or status among members, such as gender or professional status, or possibly the facilitator's skill is not well enough developed to intervene effectively. Planning to have compatible members and group-facilitator training, with feedback on performance, will ameliorate most occasions of this problem.

Analytical problems can occur when there is insufficient preparation for the collection and recording of data during a focus group. Collecting only brief comments – snippets – can occur if the size of the group is large and the time is too limited to collect rich stories. When the goal is the collection of rich, detailed data, planning needs to include adequate time for each member to speak especially for people who are not used to being in groups, and the number of questions needs to be limited in order to have time for discussion.

Ethics

Although discussion of some topics in a focus group could lead to discomfort, there is no indication that the level of distress is greater than in everyday life, and there are many reports of therapeutic effects of being part of a focus group. For very sensitive topics and for some studies with people with special needs, the facilitator needs skills to monitor the level of discomfort or distress. In addition, to ameliorate discomfort from discussing some topics, arrangements for referral for readily available support services may need to be established. The inadvertent self-disclosure of more information than a member intended is also a concern that the facilitator needs to monitor.

Ethical issues include recognizing the participants' perceptions of risks and benefits to them, to their communities, and to science. Planning includes addressing issues of confidentiality, required reporting, monitoring level of discomfort, and ethics board approval. Gaining informed consent to participate in a group is a process, not only a signed document. The reading level of the informed consent document should generally not be beyond fifth grade. When appropriate, the informed consent should include the possible future use of data, such as secondary research. Gaining informed consent verbally may be appropriate for illiterate participants and is permitted in some situations.

Confidentiality presents unique ethical challenges in focus group studies because, while the researchers can protect their use of the data, they cannot guarantee that the group members will do the same. It is unethical for researchers to promise participants that no one will disclose what is said in a session. In contrast, required reporting, such as suspected child abuse or criminal behavior, needs to be made clear to group members if the topic could involve such information. Members need to understand the consequences of disclosing such information.

Monitoring the level of discomfort, especially related to sensitive topics, and the need to have ready referral to support services should be part of planning. Debriefing of participants regarding their level of comfort after the session is recommended.

Psychosocial Foundations

By understanding the psychosocial foundations of focus groups, the researcher can appreciate the complexity of data that are collected in a group setting and can plan for optimal use of these data. The major strength, and potential problems, arises from the group dynamics in the group session. Members in the group are interactive in the sense that each comment exists in a social context and is affected by previous comments. A person adjusts the public self that others see to match what he or she understands as appropriate or in best interests of self (Goffman, 1959). *Group think* can arise in focus groups where persons whose opinions are not well formed may be swayed by the common opinion of the group (Janis, 1972). To address these concerns, the group facilitator carefully follows the comments with the goal of grounding the opinions in the key characteristics as recommended by Merton et al. (1990): depth, personal context, range, and specificity.

In a focus group session, the members and the facilitator 'co-construct' the data, developing an understanding of the experiences in the comments by responding and shaping comments. This is similar to this process in an individual interview as described by Kvale and Brinkmann (2009).

Planning

A very important component of a research study is planning. Most limitations arising from a poorly planned design cannot be compensated for with more attention later, like a stricture in a pipeline that limits the subsequent quality of the study. Planning components involved in pre-session work include facilitator and co-facilitator preparation, sampling, group size and segmenting, recruitment, introduction, guideline questions and probes, consent, transcription, translation, and a checklist.

Preparation for the facilitator and co-facilitator begins with becoming familiar with the topic and the target population. In order to plan for recruitment, conduct the session, and explore the comments, it is necessary for the facilitator to understand the comments that are likely to be made in the group, and the local context for those comments. Having logistics settled avoids distractions and the facilitator can give full attention to the task of leading the session. Another model uses co-facilitators; in this case, the roles need to be carefully identified and reviewed after each session for success and problems. Usually the co-facilitator assists with recording and room arrangements, takes notes with attention to the nonverbal communication, and summarizes at the end of the session.

Sampling in qualitative studies is purposeful and focused on sampling for the topic, not for representative sampling of the population. This may involve a broad range or a narrow and deep range, depending on the study's purpose. In many qualitative studies, preliminary analysis is performed after each data collection in order to guide future data collection. This emergent design is in accord with the grounded theory method (Corbin and Strauss, 2008), as well as other qualitative methods. As the study progresses and themes are identified, data collection will focus on aspects that are not fully developed. When new data provide no new information and themes (or categories as described in a later section), then *data saturation* is reached and the collection is considered completed. (Data saturation is the state of data collection when new data do not add new information and the theory or themes are fully developed.)

Generally, it is advisable for members of the group to be homogeneous in status, such as occupation, social class, age, and education. People are more likely to share information with others whom they see as similar. If the group is too heterogeneous, the lower-status members will likely defer to higher-status members and not contribute fully. When status is expected to impede sharing, persons may be divided into similar status groups, a process called *segmenting*. However, Carey (1994) found, in working with a military population, the common experience of having HIV or AIDS overcame the demographic differences in rank.

Previously, focus groups usually consisted of strangers who expected not to have future contact. It is now common for group members to know each other and to expect to have future contact. This has important consequences for the data quality. Members may be more reticent to share, which could lead to self-censored data. On the other hand, knowing fellow members may lead to easier conversation with a shared language and experiences.

Planning for the size of groups considers the experience of the participants with being in groups, the culture of sharing, and the sensitivity of the topic. Persons not used to sharing in groups will feel more comfortable with only three or four others, rather than eight to ten others. People need an unhurried chance to talk in order for the researcher to collect stories instead of brief snippets, which are quick, superficial comments. Five to seven people is usually a workable size, although a greater or smaller number could be optimal.

For recruitment, the researcher may use the Internet, flyers at appropriate gathering places, or work through an organization such as a clinic or school. In the latter case, this is a two-step process with the organization sending the initial invitation that includes contact information for the researcher, the purpose of the study, and how the data will be handled. A consent form may be included at this stage, or may be at a later stage. The researcher will ask if there are special needs such as food requirements (if food is to be provided during the session) or accommodations for hearing or other physical limitations. A reminder phone call the day or evening before the session is scheduled leads to fewer people who do not attend.

Most focus group sessions use broad questions as a guide for the discussion. Guideline questions provide some structure for the session. Questions are developed based on what is known and the purpose of the study, often guided by previous research. It is important to spend adequate time trying out and refining these questions, preferably with pilot sessions. Documenting changes in guideline questions as the study progresses, and explaining why the decisions were made are an important part of documenting the process of the study.

The guideline questions provide a general structure for the discussion by easing group members into a mind-set to help them describe details of their opinions or experiences. One approach is to ask a very general question to get the group oriented to the topic, and then narrow the focus to a more specific aspect of the study. However, sessions often do not proceed as the facilitator anticipated in terms of the order of the questions, usually due to the interest of the members. When possible, it is usually wise to recognize the interest of the group and follow their lead as they likely are following what is most important to them.

An alternative to using guideline questions is the watching of videos, or requesting participants to draw a picture or take a photo. This level of engagement may be particularly useful for children and others who are not used to sharing in a group setting. Also, somewhat different data may be elicited because there is evidence that words and pictures are processed in differing ways in the brain (Padgett et al., 2013). These data may be more related to emotions and may help with articulating deeply held beliefs. Potential drawbacks to using drawings in a focus group include less engagement with the group due to participants' focus on their own drawing and the societal norm for preferring positive pictures.

Analysis of the session may be done with transcripts that are note based, selected excerpts of the session, or verbatim documents. Verbatim transcripts are not synonymous with all that occurred during the session. Transcription necessarily removes some of the richness of the data in the session. In addition to possibly not being an accurate record and difficulty in identifying who is speaking, transcripts generally do not include

voice, gestures, or other nonverbal communication. Capturing the emotional context is necessary. Field notes, especially notes on nonverbal communication and group interaction, are essential to understanding the data. Video recordings also help to address this concern.

Translation of sessions conducted in a language other than one understood well by the researcher is complicated in that the translation process is not merely passive and mechanical, but rather involves the co-construction of knowledge, especially in translating for meaning as contrasted with the word-for-word approach. In this sense, the translator is participating in the research. This role needs to be made explicit and that person should be included in the analysis and interpretation of the findings.

Logistics

Details important to the successful use of focus groups include the room setting, recording procedures and equipment, and food. The room should be comfortable and afford privacy so that few interruptions will occur. Consideration may be given to holding the focus group off the premises of the organization, which is away from the physical setting associated with the research topic, to provide a psychological break and possibly encourage sharing of information.

Food is a surprisingly important aspect, and often has a role in arranging seating. In my experience, brownies were a hit with military personnel, bagels and coffee were appreciated by older citizens for a morning session in a senior center, and pizza went well with high school students. Food facilitates pre-session conversation and provides group members with something to do. This pre-session chatting, often around the food table, helps break the ice socially, but more importantly allows the facilitator to observe the members' characteristics to arrange optimal seating. The placement of individuals around a table can affect the dynamics of the group. For example, the facilitator could place an outspoken person close to her chair, so that the facilitator can better guide the level of participation of that member by turning toward or away from that person. Similarly, a shy or reticent person can be seated directly across from the facilitator allowing for eye contact and other nonverbal means of encouragement to participate. The co-facilitator may be seated back from the group in order to better observe.

Recording details, such as extension cords, duct tape to cover cords and wires, and extra batteries, should be arranged as unobtrusively as possible. After an introduction outlining the purpose of the research, the facilitator then asks permission to record the session, via audiotape or videotape. Recent improvements in technology using videotaping allow the researcher to capture more of the nonverbal aspects of members' participation, which can be helpful in placing comments in context.

Rigor

The aspect of rigor that is unique to focus groups, in contrast to other qualitative methods, is the attention needed to ensuring that the data are not negatively influenced by group dynamics. This can be addressed by attending to the nonverbal communication and following the advice of Merton et al. (1990) to collect the range, depth, personal context, and specificity of personal experiences. This is in addition to the usual recommendations of strategies employed during the study: employing an audit trail, member checks of data, adequate analysis, peer debriefing with colleagues, and negative case analysis (Morse et al., 2002). Member checks are done in the session as the facilitator checks with the participants that the facilitator has captured the main ideas. Peer debriefing with colleagues is an important and ongoing process to check that the process and insights are grounded in the data – both verbal and nonverbal data.

The goal of rigor does not vary with different research purposes; rather, the level of detail in analysis varies. For readers to evaluate the worth of the study findings, they need to know not only what was found but also how it was found. Adequate details need to be provided of the process of moving from raw data to codes, to categories, and to themes, depending on the purpose of the study. Verification strategies that are used to enhance reliability and validity of the research process include methodological coherence, concurrent data collection and analysis, and theory development as appropriate to the research purpose.

Conducting the Session

Topics to consider in preparing to conduct focus group sessions include group management skills, starting the session, session structure and facilitator role, probing (follow-up questions for more detail), and handling problems. Facilitator skills include monitoring discomfort, guiding the discussion, and enhancing data quality. It is the responsibility of the facilitator to monitor the level of distress and refocus the group; and in unusual cases, to stop the session when necessary if a member becomes distressed. Listening to 'what is behind the words' spoken – active listening – can be learned through practice and feedback. The facilitator encourages participation while maintaining a nonjudgmental style. Avoiding nodding after a comment will prevent the perception of the comment as 'correct.'

When one or two members dominate the conversion, participation of others is limited. In addition to thanking the talkative person and turning to the group to ask for other comments, the facilitator can indicate that other comments are welcome. If the talkative person has intentionally been seated next to the facilitator based on the pre-session mingling, the facilitator can slightly turn her/his body away from the talkative person to face others, thereby nonverbally reinforcing the norm of other contributions. It is important to not be too brief with a chatty member, or the rest of the group will feel somewhat chastised also and be more reticent to speak. When the talkative person has been recognized for his/her contribution, no offense will be taken. On the other hand, by seating a quiet person directly across from the facilitator, the facilitator can encourage participation by making eye contact and restating the goal of listening to a range of experiences.

A major concern for data quality is the potential for a 'group think,' the phenomenon of participants being carried along by the group interaction and agreeing with the overall discussion

(Carey and Smith, 1994). It is usually apparent when this is occurring and is a challenge for the facilitator to explore. Going back to Merton and colleague's (Merton et al., 1990) advice to explore the depth and specific details can help to address this challenge. It is important not to directly challenge, but to ask for more information.

The facilitator begins with an introduction to the session. The introduction includes information about the project and the sponsoring organization that was previously provided in the recruitment letter or phone call, and answers any questions. Agreement for recording will have been obtained earlier as part of the consent process and it is repeated here before the video- or audiotaping is begun. Depending on the purpose, the members are told that a range of experiences rather than agreement is the goal. Members are encouraged to share comments that are not necessarily in agreement with each other, and members can feel comfortable to describe a range of opinions because it is made clear that there are no correct responses. Some knowledge of the topic and of the participants is needed to understand the comments well enough to guide the discussion and ensure quality of the data in terms of rich, detailed comments. Two simple, helpful 'rules' are (1) no disparaging remarks about another member's comments, and (2) only one person talking at a time. The request for one person at a time to speak prevents comments from overlapping. Cell phone and pagers are turned off, or if necessary for participants to be reachable, turned to quiet mode.

The purpose of the study guides the decisions on the amount of detail in the guideline questions and in the flexibility in following the questions. For an exploratory topic, less direction from the facilitator, more flexibility in following the questions, and more openness of the questions can allow unanticipated findings to arise that involve issues of importance to the members. The facilitator needs to have ongoing engagement with data to appreciate how the stories are related and how the synergy in the group is influencing the comments. Asking members to 'think back' to the experience can help put them in the setting and bring out some of the richness of their experiences. The 'ice breaker' question is an easy way to open the discussion and gets members comfortable with speaking in the group. A brief, factual question, such as "when did you receive your diagnosis and how did you learn of it," is easily answered as the participants take turns going around the group.

When the discussion is ready to move on to the next question, it is helpful to briefly summarize the main ideas (not characterized as a consensus), at the end of each question. The flow of the discussion may not permit this to be done comfortably, and it is not necessary for each question. A review of the main ideas at the end of the session, 'member checking,' is checking of main ideas for accuracy of understanding of the data collected. It is important to leave time for the last question – "If you could tell the organization just one thing, what would it be?" This last question often elicits the most useful data. Members have been discussing the topic and are usually eager to state their ideas.

Many topics in focus group studies will not lead to any stress or embarrassment, but some could. It has not been my experience, or the experiences of my colleagues, that conflict or embarrassment occurs. Appropriate planning and facilitating skills should lessen the probability of these occurrences. The facilitator monitors stress levels and intercedes to guide the discussion in a safe direction, or in extreme and very unusual cases, the session may be stopped and referral services arranged. When facilitating sessions on sensitive topics, it may be helpful to allow members to describe a friend's experience. The researcher may suspect that the 'friend's' story is actually the member's experience, but the member chooses to tell the story in another's voice. The detachment may arise from a concern that the group will think poorly of the member's comments. The researcher will judge how much to further question and how much to accept without inquiring further into the details.

Probing

The most important aspect of guiding the session to elicit good-quality data is knowing when and how to follow up, or probe. A preliminary type of analysis while conducting the sessions guides the facilitator in seeking further information, more details based on personal experience. Lack of agreement between verbal and nonverbal communications, and inconsistent comments can be bases for probing. Personal and specific details improve the credibility and general quality of the data. It is important to note a change in a participant's opinion during the session and try to determine what led to the change.

Analysis

The goal of analysis is the development of a clear and convincing picture of findings. Because there are few guidelines available, the researcher needs to thoroughly understand the psychosocial context of the data; the various analytic methods available; and the importance of methodological coherence of purpose, process, and product. The goal is to understand the participants' experiences and to communicate the findings so that they may be readily used.

A study's findings can be data rich and analysis poor; that is, they are underanalyzed to address the study's purpose. There are few, if any, agreed-on rules for qualitative analysis of focus group data. This is mostly because this technique, as a data collection method, can be used with different methodologies. From a general review of the literature, it appears focus groups are used most often with grounded theory.

Because each study is unique, guidelines need to be used with creativity and judgment. Charmaz (2006) recommends "imaginatively engaging" with the data and then solidly grounding the interpretation directly back in the data. This recommendation encourages the researcher to explore the possibilities that are not immediately obvious, thereby examining patterns that at first are not apparent. This approach can produce new and important theoretical development.

Some qualitative research methods are not distinct from each other. Approaches range from staying quite close to the data and identifying broad themes to developing explanatory theory through interpretation and synthesis. Most qualitative methods used with focus groups' studies have several components in common: identification of a topic, selection of a population, collection of data, inductive coding and further

iterative grouping of concepts, prioritizing of key ideas, and the use of the researcher as instrument in data collection and analysis. The most commonly used methods in published studies of focus group research include thematic analysis (Braun and Clarke, 2006), discourse analysis (Fairclough, 1993), content analysis (Elo and Kyngas, 2007), narrative analysis (Reissman, 1993), and grounded theory (Corbin and Strauss, 2008), and there are many variations of each of these. It is beyond the scope of this article to further explore the potential for each method.

Software can be a helpful tool to organize the large amounts of data that are often involved in a project. It does take time to master a software program in order for it to be a helpful tool and not a nuisance. Newer programs are capable of using videotapes and some have voice recognition capability to provide rapid transcripts. Some software programs promise to describe group dynamics beyond what researchers can do with other software. This automatic coding and grouping will likely be met with skepticism by some researchers who value the in-depth involvement of the researcher in understanding the text. It will be interesting to keep an open mind and see what enhancements will be helpful as technology continues to advance.

Reporting

This component should be included in the planning phase as an overall structure can guide the study. Consider who will use the information and how they could use it. In addition to the elements common to research reporting, the only element unique to focus group research reporting is the group context of the data. Emphasizing the verification strategies and rigor will assist the readers in evaluating the worth of the study. Please see Carey and Asbury (2012) for a helpful format.

Looking Ahead

The goal of this article is to present the rich potential of focus group research and provide some guidance in planning. Most of the literature on recommendations, although based on psychosocial frameworks, is based on personal experience. What is needed to improve is empirical research, such as the relative impact of group size, segmenting, stranger versus familiarity among members, relative structure in a session, matching demographics of facilitator and members. Technology will increasingly be used and the effects on data need to be explored.

Overall, focus group data collection is a technique that yields rich data that could not be obtained through other means. It is well worth the time and effort to plan and implement it in a study.

Folklore

Barbro Klein, Swedish Collegium for Advanced Study (SCAS), Uppsala, Sweden

Abstract

Coined in 1846 to describe the customs, superstitions, and arts "of the olden time," folklore was in the 1990s defined as "expressive forms, processes, and behaviors" that are learned and utilized in face-to-face interaction and are judged to be traditional. This article addresses different understandings of the term along with theories proposed to account for the origin, spread, and functions of epics, games, rituals, and other folklore phenomena. In special focus are six keywords: folk, tradition, genre, performance, text, and art. Also addressed are the role of folklore study around the world today and its role in global heritage politics.

Folklore can be said to have four basic meanings. First, it denotes oral narration, rituals, crafts, music making, and other forms of vernacular expressive culture. Second, folklore or folkloristics names an academic discipline devoted to the study of such phenomena. Third, in everyday usage, folklore sometimes describes colorful 'folkloric' phenomena linked to the music, tourist, and fashion industries. Fourth, like myth, folklore can mean falsehood. Although in this article, focus is placed on the first two meanings, the other two are often present, implicitly or explicitly.

History

A Term Is Invented

The word folklore (spelled 'folk-lore') was proposed by British antiquarian William John Thoms who, in 1846, suggested that this "good Saxon compound" be used to describe "the manners, customs, observances, superstitions, ballads, proverbs," and other materials "of the olden time." Thoms was inspired by the works of the Brothers Grimm, and 'folklore' is apparently a translation of the German word *Volkskunde*, which was introduced in 1806.

Although the word was new, interest in the phenomena themselves was not (Cocchiara, 1981 (1952)). European and Asian rulers had long ordered that traditions that would glorify them be written down, and religious leaders had compiled records of dangerous beliefs in order to weed them out. However, during the national romantic currents of the late eighteenth and early nineteenth centuries, European intellectuals added something new when they insisted that the customs and arts of illiterate peasants were remnants from a remote human past and should be collected and preserved before they were bound to disappear as civilization advanced. Like Johann Gottfried von Herder, intellectuals saw a reflection of the true spirit of nations in the traditions of the anonymous folk living close to the national soil.

A Discipline Is Founded

During the nineteenth century, many people were fascinated with folklore, among them scholars with interests in literature, philology, religion, psychology, history, archeology, anthropology, and other fields. In some countries, enthusiasts formed societies: the British Folklore Society was founded in 1878, and the equivalent in the United States 10 years later. In other countries, primarily in Northern, Central, and Eastern Europe, the idea of folklore was directly linked to nation formation. In Finland, which was in the process of freeing itself, first from Swedish and then from Russian domination, Elias Lönnrot pieced together the *Kalevala Epic* from songs collected in the oral tradition. Published in 1835, the *Kalevala* became the first example of literature written in Finnish and a national symbol. In addition, the songs formed the core of a national folklore archive, and, in 1898, the world's first professorship in folklore was established: the chair in Finnish and Comparative Folklore at the University of Helsinki.

Other university departments were eventually established in some countries in Europe, East Asia, South America, and North America, usually (but not always) in conjunction with the founding of national museums and archives. These institutions could have different designations (e.g., folklore, *Volkskunde*, laographia, folk memory research, folklife research, or ethnology) or could emphasize different empirical traditions. The varieties in political and cultural histories and national styles were significant, even though both the fields of study and the academic institutions grew out of a similar spirit of nation building.

At the same time, anthropologists concentrated on the folklore of colonized (or tribal or indigenous) peoples, whether or not these peoples were in their own country or in colonies far away. It has sometimes been observed that "folklore grew out of nationalism while anthropology grew out of colonialism." There is some truth to this in so far that, to this day, anthropologists (nowadays often indigenous anthropologists) tend to study the folklore of indigenous, illiterate, or 'oral' populations, whereas folklorists tend to focus on literate (albeit often subaltern) people in their own countries. The United States constitutes a noteworthy case in so far that the discipline of folklore developed hand in hand with a protracted "dialogue of dissent" between anthropologists, such as Franz Boas who worked with Native American folklore, and literary scholars, such as Francis James Child, who concentrated on Euro-American traditions (Zumwalt, 1988). In the United States and elsewhere, early research traditions set the stage for political and ideological entanglements that have actuality to this day (see Section Folklore and the Politics of Culture and Heritage).

It should be emphasized that many (if not most) countries in the world lack academic institutions of folklore and that the field tends to be studied within other disciplines or outside formal academic institutions. England, for example, has never established university departments devoted to folkloristics, whereas Scotland, Ireland, and Northern Ireland have deemed it politically and linguistically important to do so.

A History of Approaches

On the whole, the ideas employed to explain and interpret folklore coincide with the major schools of thought in anthropology, beginning with evolutionism and diffusionism and moving on toward functionalism, structuralism, and later tendencies. Yet even more than in anthropology as a whole, the study of folklore long focused on questions of origin; an array of explanations were proposed to account for the origin of such ancient and widely disseminated tales as "The Dragon Slayer" and other traditions. The Indianist school headed by the German orientalist Theodor Benfey sought to establish that all European folktales had originated in India and spread from there. The mythological school, championed by the German-born orientalist Max Müller at the University of Oxford, maintained that all folktales were survivals of ancient nature-myths, whereas ritualists, such as the French folklorist Pierre Saintyves (Émile Nourry), tried to demonstrate that all folktales had originated in rituals.

While these explanations now have primarily historical interest, other early trends of thought remain intellectually influential. Among these is, first, the diffusionist 'historical–geographical' method developed by Finnish scholars at the end of the nineteenth century. In this cumbersome procedure, all recorded versions and variants of a tale type (or a ballad or a riddle) are studied so that the location of the earliest traits, and theoretically also the tale's place of origin, can be determined. The gathering of comparative evidence resulted in massive indexes and catalogs that are still often consulted (Aarne and Thompson, 1961; Uther, 2004). Another intellectual movement that remains important to the understanding of folklore is psychoanalysis (Holbek, 1987). Sigmund Freud, Carl G. Jung, Otto Rank, and others came to regard folklore as essential expressions of the individual or collective human unconscious. A third essential strand of thought is the insight that forms of folklore are not only widely spread but also firmly localized and therefore must be studied in their immediate social contexts. Franz Boas' ethnographies of the stories of native peoples on the northwestern coast of the United States initiated an influential format for the study of folklore in local contexts.

Functionalism, not least Bronislaw Malinowski's analyses of storytelling among the Trobrianders, is a fourth development that has had a lasting impact on the study of folklore. Particularly influential is the psycho-functionalist premise that folklore is "socially sanctioned" fantasy; as such, it permits action that is otherwise not approved (Dundes, 1965: p. 277). Finally, structuralist thought has also endured among students of folklore. One structuralist approach derives from Russian formalism and emphasizes features of plot sequence; in an influential study, Vladimir Propp demonstrated that all Russian fairy tales share the same plot structure (Propp, 1968). A second approach derives from the work of Claude Lévi-Strauss and points to the ways in which logical relationships within myths and tales, such as binary oppositions, reflect universal processes of the human mind. Lévi-Strauss' thinking has been central to the analysis of a wide range of traditional forms, not least Henry Glassie's monumental investigations of vernacular material culture (1982, 1993).

Keywords

Despite the many decades of inquiry, it remains difficult to define folklore. In one attempt proposed in the 1990s, it was suggested that folklore embraces "expressive forms, processes, and behaviors" that are learned, taught, and utilized "during face-to-face interactions"; it was also noted that people judge these phenomena to be traditional "because they serve as evidence of continuities … through time and space in human … thought, belief, and feeling" (Georges and Jones, 1995: p. 1). However, increasingly scholars avoid such generalized statements. In their search for "a common ground for a disciplinary discourse" (Bendix and Hasan-Rokem, 2012: p. 2), they prefer instead to look at folklore as perspectives and processes that might be illuminated through such keywords as "folk," "tradition," "genre," "performance," "text," and "art" (Feintuch, 1995, 2003).

Folk

Influenced by the typologies of early social thought and by such conceptualizations as Robert Redfield's "ideal folk society," students of folklore long took it for granted that the folk (i.e., the carriers and transmitters of folklore) were illiterate peasants or tribal peoples. However, during the last few decades, the word 'folk' is increasingly regarded as a cumbersome inheritance from earlier thinking, and most researchers agree that all human beings in some way or another are involved in folklore processes, as performers, participants, watchers, viewers, readers, or audiences – sometimes indifferent or disdainful audiences (see Section Performance, Text, and Art).

But it has been difficult to abolish the word 'folk.' For one thing, it remains important in studies of folklore in feudal systems or other class hierarchies. Second, it remains alive in such compounds as 'folk art,' 'folk music,' and 'folk dance'; attempts to replace 'folk' with 'people,' 'vernacular,' or other words have not been successful (see Section Folklore and the Politics of Culture and Heritage). Furthermore, despite their conviction that all human beings partake in folklore processes, contemporary folklore researchers resemble their predecessors in concentrating on marginal or subaltern peoples. But their reasons for doing so may differ from those of nineteenth-century scholars; many students now argue that the role of folklorists is to assist peoples who lack political power in their quest to gain a public voice.

Tradition

Used both to designate a process of transmission and to name specific repeatable and retrievable cultural elements (i.e., traditions), the concept of tradition is basic to the understanding of

folklore and folkloristics (Bauman and Briggs, 2003). It has long been recognized that tradition involves not only historical continuity but also change. Because folklore forms are often transmitted orally or in other informal ways, they are extremely adaptable to fleeting moments of social interaction. One could even say that it is because of their adaptability that simple string figures or guessing games have remained in circulation through millennia.

The materials deposited in archives, listed in comparative indexes, and appearing in popular culture demonstrate both the adaptability of some themes and their continuity through time and space. For example, comic book hero Superman travels through space in a womblike vessel only to be found and raised by a poor couple in the middle of North America. His story has parallels with the stories of Moses, Cyros, and other heroes who are similarly found as children floating around in small containers. Furthermore, identity changes are characteristic not only of Superman but also of countless other heroes and heroines in world traditions. The transformation of an orphaned young girl into a rich and beautiful queen is reenacted over and over in oral tales, films, and real life. Folklore themes have a psychological force that makes people recreate them century after century in different communicative modes and media (Bacchilega, 1997).

During recent decades, students of folklore increasingly utilize the verb 'traditionalize' to name processes in which the past is interpreted or reinvented in a given present. Many students of folklore now emphasize that they do not investigate given sets of traditions, but all sorts of practices of traditionalization in social life. Furthermore, by focusing on active traditionalization processes, scholars avoid cementing an opposition between tradition and creativity. They see tradition as a source of creativity, not as a constraint to it (Briggs, 1988; Bauman, 2004).

Genre

Genre means 'kind,' and a genre may be seen as a distinguishable form characterized by a specific combination of stylistic traits and elements of content. Classification into genres was for a long time so central that scholars thought that enumerating genres was the easiest way to describe what folklore is (Dundes, 1965).

When analyzing genres, students of folklore often find themselves caught in dilemmas familiar to all students of culture. On the one hand, all peoples make local, culture-specific, or 'emic' distinctions between genres in their repertoires: coyote tales, superstitions, dirty jokes, little girls' games, gossip, songs while making baskets, and so on. On the other hand, scholars may observe more overriding features in the same materials and may note how elements of content, style, or structure are shared across cultural boundaries. The extent to which local classifications are emphasized and the extent to which broader ones come into play vary with different analytic tasks.

One distinction that was long taken for granted but has proven problematic is that between 'fixed' genres, such as riddles and proverbs, and 'unfixed' genres, such as legends or anecdotes. While some genres, magic formulas for example, are fixed in the sense that they must be recited exactly as learned in order to have power, other genres that were long called 'fixed' may change too. For example, people often do not cite proverbs in full but merely hint at them through their tone of voice. Thanks to performance-centered approaches (see Section Performance), scholars have recently gained new insights into the ways in which oral genres are malleable social phenomena. In social interaction, people mix or blur materials so that artful hybrids emerge. At the same time, genres are needed as 'social contracts' that aid memory and establish structure.

Performance

Since the 1960s, the concept of performance has transformed the study of folklore. Thanks to increasing refinements in recording techniques, scholars have been able to analyze folklore as part of communicative processes in ways that had not been possible before. Two performance-centered approaches will be recognized here; in both, careful ethnographic fieldwork is essential.

One approach is rooted in ethnography of speaking and other sociolinguistic methods. A basic idea is that verbal art and other forms of folklore emerge in social interaction as aesthetically marked forms. They are recognized as something special thanks to cues made through tone of voice, mimicry, gestures, and other paralinguistic devices. Arguing that performance is "constitutive" of verbal art, Dell Hymes, Richard Bauman (1977), and others developed ways of studying folklore as artistic communication in everyday life, communication in which people shape "deeply felt values into meaningful, apposite form" (Hymes, 1975: p. 346). If epic singers, storytellers, weavers, carvers, and carnival participants in the past were seen as transmitters of handed-down traditions, they were now regarded as active artists with power to transform social life (Mills, 1991).

A second performance-centered approach is oral formulaic theory, which was first developed by Albert Lord (1960, 2000) and others who, in studies of South Slavic oral epic poetry, show how songs that are many thousands of lines long can live in tradition, although they have not been written down. They persist because singers learn to draw on a store of formulas and formulaic expressions and learn to adjust their singing to different social events. Several scholars have continued along these paths, and oral formulaic studies are now enriching the understanding of both ancient (in particular, Homeric) epic singing and contemporary performances of epic songs and other forms of oral poetry in India, China, Africa, Eastern Europe, and the United States (Finnegan, 1992; Honko, 1998; Foley, 2002).

Text

It has long been recognized that the distinction between oral and written texts is far from firm and that many kinds of texts can be of interest to students of folklore (Hasan-Rokem, 2000). Some folklore texts have led their primary existence in writing, for example as court records, religious documents, or newspaper articles, and today we find countless texts and expressions on the internet that are of interest to students of folklore. Other folklore texts have circulated primarily as visual representations, for example fables painted inside European medieval churches and so-called xeroxlore. Furthermore, literary authors have continuously made use of traditional themes, and folklore texts can be located in the works of celebrated writers. For example,

contemporary African authors, such as Ayi Kwei Armah, acknowledge their profound debt to oral narrative art, and Shakespeare often built his plays on traditional materials. Actually, a great many art forms can profitably be studied as folklore texts. Classical ballet, for example, shares some of its stylized and repetitive character with the European folktale.

During the last few decades, performance-centered approaches have opened up oral texts in unprecedented ways in that scholars have invented new methods to translate oral performances into writing. In procedures that have sometimes been named "laying out texts ethnopoetically," students transcribe not only words but also pauses, cadences, gestures, mimicry, and other oral features (Briggs, 1988). These procedures have led to many insights. One is that oral narration in many cultures tends to be closer to drama than to prose literature. Another is that repetitions and other features of oral narration (or visual folk art) are not to be dismissed as poor artistry as was often the case in the past. Rather, repetitions can be seen as ways to control complex materials. A repetitive structure simultaneously offers restrictions and creative freedom; it aids memory at the same time as it frees fantasy and improvisation.

During the last few years, the term 'textualization' is increasingly used to describe modes of translating oral performances onto the written page (Honko, 1998). Long regarded as routine exercises, textualization processes are now seen as central analytic tasks.

Art

On some level, scholars always seem to have agreed that folklore has to do with art, creativity, and imagination. Even at times when the study of folklore was reduced to enumerations of genres and tale types, there was a sense that folklore touches upon the aesthetic dimensions of life. This sense has become heightened during the last few decades, in part due to the interest in folklore as performance. This is particularly the case in the United States, where all kinds of vernacular expressions – from singing to cooking and quilting – are often called 'the folk arts.'

The focus on art is linked to several perspectives. First, students make a distinction between less articulate folklore performers and artists who are celebrated in their communities and have the power to move others to action. Second, students of folklore have made important discoveries about social life by focusing, not on finished products, but on moments when material objects or community events are being planned or created. Third, an interest in art has led to new analyses of the languages of folklore. Whether verbal, visual, musical, kinesthetic, or tactile, these languages are bold in their use of intense and multivalent metaphors and other tropes.

It is because of this expressive intensity that folklore, like other forms of art, can be a vehicle through which people can examine or critique the lives they lead (Scheub, 1998; Noyes, 2003). For example, to people who have fled from one part of the world to another, a few songs, stories, or dishes can become embodiments of a precious inheritance that must be preserved and reconstituted in new lands. Conversely, folklore can incarnate some of the worst aspects of life: detested symbols of racism or sexism, humiliating jokes that outsiders direct at one's own group, and rumors and legends that demonize people(s) (Goldstein, 2004). Because of its power of presence, folklore can be invoked to hold communities together or to separate them from one another.

Folklore and the Politics of Culture and Heritage

Among contemporary scholars, there is both confidence and unease about the future of folklore and folklore study. There is confidence, for example, about the supply of material. The idea that folklore is 'dying out' is no truer today than it was 200 years ago (Bausinger, 1990 (1961)). People shape rituals and tell stories, perhaps more than ever before, but they do so not only in face-to-face interaction but also on electronic media. There is also confidence in the sense that interest in the field continues to expand. For many, the study of folklore constitutes a crucial approach to understanding human life (Briggs and Shuman, 1993). Some scholars are convinced that, regardless of the discipline to which students of folklore belong, today these students play a special role as advocates of the artistic expressions and traditions of all those groups and individuals who are caught in the cracks of modern life. Most notably, there is a heightened interest in folklore and the study of folklore outside of Europe and North America, both among native scholars and among scholars from other countries (Yankah, 1989). This is particularly true in Asia, primarily in China and India, where the number of folklore departments is increasing; but there is new interest also in Africa (Peek and Yankah, 2004). In part, these developments are a result of critical reflections on the discipline's long Eurocentric and colonial history (Naithani, 2010). Folklore researchers on all continents now recognize the need for a thorough revision of the history of the field, a revision in which Asian, Latin American, African, and Oceanic perspectives are highlighted (Bendix and Hasan-Rokem, 2012).

But at the same time, there is uncertainty about the directions of folklore study. The prevalence of folklore on the internet has led folklorists to wonder how understandings of folklore will have to be modified. Does it still make sense to speak about 'face-to-face interaction' or even about 'the social base' of folklore? Many uncertainties and critical reflections concern the discipline's often naïve, and sometimes disastrous, ideological and political entanglements, not least in Europe (Bendix, 1997). Among the indications of these uncertainties are the seemingly never-ending controversies surrounding the designation of the field. In Germany, the term *Volkskunde* is now often avoided, because some practitioners were deeply involved with the creation of symbols for the Third Reich, and in France the word 'folklore' still resonates with memories of fascist scholarship. In most European countries, 'ethnology' is now preferred to compounds containing 'folk' as an overarching disciplinary designation (see Section Folk).

Many uncertainties concern the paradoxical situation that the study of folklore is almost everywhere a construction in the-service of nation building and related local endeavors at the same time as it regards itself an international field. As was the case in the nineteenth century, national concerns often continue to prevail over international and transnational ones. For example, in

nations reconstituted after the fall of the Soviet Union, folklore and folklore archives play a critical role in efforts to select and (re-) construct visions of exclusive national heritages. In other countries, the links to nation building can take other expressions. In the United States, for instance, folklore and folklorists have become important in affirming a vision of a country in which a multitude of diverse cultures can coexist. This is particularly true of so-called public folklorists (Baron and Spitzer, 2007). Whether they are employed in museums; at the American Folklife Center in Washington, DC; as state folk arts coordinators; or in privately funded endeavors, these professionals have special skills in collecting, preserving, and presenting the folklore of (and with) an immense diversity of groups.

On a global level, folklorists are now entangled in cultural politics and heritage politics, perhaps more than ever before (Kirshenblatt-Gimblett, 1998). In the last few decades of the twentieth century, folklorists worked with UNESCO in efforts to safeguard folk traditions around the globe from the onslaughts of modernization. These efforts assumed new dimensions in 2003, when (31 years after adopting a convention concerning material heritage) UNESCO adopted the Intangible Cultural Heritage Convention (ICHC), which, in 2012, was ratified by 148 countries. To a great extent, the phenomena selected as intangible cultural heritage "in need of urgent safeguarding" (such as Iranian Naqqali storytelling) or selected as "representative" (such as the celebration of *nowruz* in several Asian countries) have long been studied within the purviews of folkloristics.

The 2003 UNESCO convention has encouraged national or local community endeavors to increase their efforts to appoint certain forms of folklore and other cultural materials as worthy of preservation. These efforts raise many questions concerning ethics, intellectual property rights, identity politics, and local ecologies and economies, not least those involving tourism. Is the protection of selected phenomena always morally good, valuable, and harmless? In whose interest are the efforts being carried out? Whose traditions should be safeguarded, and whose should be deleted? To what extent will protection freeze certain forms and ideas and appoint them as the correct and authentic ones to the detriment of other traditions?

The preservationist impulses that have guided the field of folklore since Herder's days (and before) are now assuming bureaucratic proportions that were once unthinkable. Undoubtedly, different kinds of heritage politics and policies and a variety of ideological mazes will become important foci of attention for folklore researchers in years to come. In the meantime, people will go on making music, telling stories, playing games, performing rituals, and whittling toys – in their families, on the social media, or to attract visitors to festivals and performance sites. To scholars, it is important to recognize and investigate the multitude of levels and perspectives that are involved in the study of folklore.

Food Deserts in US Cities

Amy M Donley and Marie C Gualtieri, University of Central Florida, Orlando, FL, USA

Abstract

Food insecurity is a worldwide problem experienced by millions of people. A specific manifestation of food insecurity has been documented in cities of the United States. It is related to the so-called food deserts, urban areas where individuals make up for the lack of supermarkets located in their vicinity by eating at nearby fast food restaurants and shopping at local convenience stores where they buy generally unhealthy food. The number of individuals living in food deserts in the United States, or in other countries, is unknown because there is no standard definition for the term 'food desert.' Food deserts are viewed as a form of constructed inequality because their distribution is not an accidental, naturally occurring phenomenon. For local officials to address the issue of food deserts is of the utmost importance, as there is a need for alternative ways to supply urban residents with nutritious, affordable foods.

Global Hunger

In 2013, 842 million people in the world are experiencing chronic hunger, meaning they do not have enough to eat daily (FAO, IFAD, and WFP, 2013). The majority of individuals facing chronic hunger and malnourishment reside in developing countries. More specifically, Asia has approximately 552 million individuals facing hunger, which is the largest concentration of individuals experiencing food insecurity worldwide (FAO, IFAD, and WFP, 2013). On average, 1 in 6 children residing in developing countries is underweight, and annually, poor nutrition is the cause of death for approximately 3.1 million children (Black et al., 2013). Even while malnourishment and hunger exist in these places, developing countries are progressing toward the first goal of the Millennium Development Goals set forth by the United Nations, which is to "eradicate extreme poverty and hunger by 2015" (FAO, IFAD, and WFP, 2013). While the 2015 goal has already been met in some areas of the world, other areas have either made no progress or will not meet their goal if their current trend of ending hunger continues. Therefore, despite efforts, hunger is still a serious problem that people continue to experience globally (Millennium Development Goals, 2013).

According to the Food and Agriculture Organization of the United Nations, policies seeking to improve agricultural production and increase food accessibility would ultimately reduce hunger in areas where food insecurity is prevalent (FAO, IFAD, and WFP, 2013). More specifically, these policies could support markets in these areas, provide employment opportunities, and thus, lead to economic growth, while reducing food insecurity (FAO, IFAD, and WFP, 2013). Public policies toward gender equality have also been suggested as a way to reduce food insecurity; in many countries, women farmers have less access to resources (land, capital, credit, markets) compared to their male counterparts. If women had the same amount of resources to use, then it is estimated that the number of individuals facing hunger would decrease by 150 million (Food and Agriculture Organization of the United Nations, 2011). Remittances are also discussed as a way to reduce hunger and boost economic well-being (Bassett, 2010; FAO, IFAD, and WFP, 2013). Remittances are when individuals send some of their paycheck back to family members in their home country, typically a less developed country. This source of income provides family members with money for food and to cover expenses. Additionally, in the bigger picture, the money gets put into the country's economy in which it is spent. By giving people more power in terms of food systems, known as food sovereignty, ongoing relationships can be created between food providers and consumers, as well as a relationship between local land and the residents that use it.

While hunger occurs globally and mainly in the developing economies, this article examines the issue of hunger in relation to *food deserts* experienced in the United States. The phrase 'food desert' does not translate universally. By the US standard, a large portion of the world would qualify as a 'food desert.' But contrary to world opinion, there are still hungry and food-insecure people in the United States and a major contributing factor are the large number of 'food deserts' in US cities.

This article addresses the multiple definitions of food deserts, theories of how these areas developed in the United States, problems and controversies, and alternative food sources that could be used as solutions to food deserts.

Hunger in the United States

Food insecurity in the United States has no boundaries. The issue of hunger impacts individuals of different socioeconomic backgrounds, geographical locations, ages, genders, and races (Hunger Facts, 2012). In a recent report, Coleman-Jensen et al. (2013) found that 49 million Americans experienced food insecurity, with 33.1 million of those individuals being adults and 15.9 million of them being children. Additionally, 4.8 million seniors aged 60 and older are experiencing food insecurity (Ziliak and Gundersen, 2013). The issue of food insecurity transcends just hunger, it also impacts childhood development and exacerbates health issues among many adults and seniors (Bhargava et al., 2012; Bhattacharya et al., 2004; Cook et al., 2004; Holben, 2010; Rose-Jacobs et al., 2008; Skalicky et al., 2006; Stuff et al., 2004).

Food insecurity is measured on different levels: least severe, moderately severe, and more severe (Cook et al., 2004).

The difference among these levels lies with how food is rationed within households. Least severe is described as making adjustments to one's diet and variety of food. Moderately severe is described as cutting the sizes of meals and the amount of food intake. More severe food insecurity takes place in households typically with children. Usually, adults will reduce their food intake before the children. However, in a 'more severe' household, the child's intake is reduced as well because there are no other options.

In the standard United States Department of Agriculture (USDA) questions used to measure food insecurity, the problem is *defined* as lacking enough money to buy the amount and variety of food one needs or wants. It is therefore worth noting here that food insecurity can also result from mobility and disability issues (unable to get to food outlets), cultural preferences (nearby stores do not carry the food products a household would normally eat), or insufficient social capital (no one to help in procuring the food one needs.)

What Is a Food Desert?

The issue of food insecurity is centered on the '3As': Accessibility, Adequacy, and Affordability. While the term was first developed in the United Kingdom (Cummins and Macintyre, 1999), according to the USDA 'food deserts' are defined as "urban neighborhoods and rural towns without ready access to fresh, healthy, and affordable food. Instead of supermarkets and grocery stores, these communities may have no food access or are served only by fast food restaurants and convenience stores that offer few healthy, affordable food options" (Food Deserts, 2013). This definition specifically describes low-income neighborhoods. While this definition is used nationwide, it may miss the differences found in the food deserts of urban and rural areas. In urban areas, a location is deemed a food desert if there is no accessibility to food within a one-mile radius. In rural areas, a location is considered as a food desert if there is no accessibility to food within a ten-mile radius (Berg and Murdoch, 2008; Sparks et al., 2010; USDA, 2009; Wrigley et al., 2002). Food deserts, typically low-income communities, are areas that experience a special type of food insecurity. Food deserts are 'insecure' because there is no adequate food, meaning deemed appropriate to consume by the USDA's food pyramid guide, to purchase within a manageable distance from an individual's residence. The establishments where food can be found typically lack variety and nutritious food. However, these foods are not necessarily affordable and the lack of nutrition has caused an abundance of health issues among residents of these food desert areas (Andrews et al., 2013).

However, the USDA definition of a food desert is not the only one. Other definitions include, in addition to the geographic proximity, the elusive nature of accessing nutritious foods due to physical and economic barriers (Reisig and Hobbiss, 2000). Others focus on the quality of food available to residents and the affordability of those foods based on the socioeconomic condition of residents in the community (Cummins and Macintyre, 2002; Reisig and Hobbiss, 2000; Walker et al., 2010). One study operationalized the term 'food desert' as "urban areas with 10 or fewer grocery stores and no stores with more than 20 employees" (Hendrickson et al., 2006). These alternative definitions are used because rather than being concerned with just the factor of nutrition, these researchers were more concerned with the type, size, and number of stores available to residents and not necessarily the quality of food (Hendrickson et al., 2006).

Theories on How Food Deserts Formed in the United States

Researchers propose different theories to explain how food deserts emerged in the United States. One theory is that chain supermarket stores have put smaller, neighborhood 'mom and pop' grocery stores out of business (Cliff et al., 2004). These local 'mom and pop' stores are forced to close from the enticing visions created by these large supermarkets; they have large parking lots, longer hours, and some even offer to bag your groceries and bring them out to your car, something small stores cannot offer. However, these types of 'mega stores' are only available for those who have cars or can access and afford public transportation (Cliff et al., 2004). Without transportation to these locations, many are left with doing their grocery shopping at convenience stores where nutritious food is less available (Hendrickson et al., 2006).

Other researchers argue that food deserts arose in inner-city areas because the median income dropped when affluent residents migrated to suburban areas in the 1960s through the 1980s (Bianchi et al., 1982; Flournoy, 2006; Nyden et al., 1998; Wienk, 1979; Walker et al., 2010). Studies show that this migration to suburbs from urban areas resulted in closing of one-half of the supermarkets in the three largest cities of the United States (Alwitt and Donley, 1997; Diesenhouse, 1993; Miller, 1994; Walker et al., 2010). The same migration caused a significant decrease in the median income of the inner-city areas, transforming many aspects of these cities. The migration to suburban areas also resulted in fewer places to purchase groceries. Shaffer (2002) explored the gap of supermarkets between lower-income, inner-city areas and middle-income, suburban communities in Los Angeles, California. She found that middle- and upper-income communities have twice as many supermarkets as low-income communities. Specifically, white residential areas had three times the supermarkets than black residential communities. Other studies analyzing access to grocery stores in communities by racial composition and poverty produced similar findings (Morland et al., 2002; Powell et al., 2007a; Zenk et al., 2005). Morland et al. (2002) collected data on the dietary intake of residents participating in the Atherosclerosis Risk in Communities Study to examine the local food environment's impact on nutrition. These communities were located in Maryland, North Carolina, Mississippi, and Minnesota. Findings suggested that census tracts in which white Americans resided had 5 times the number of supermarkets that black American neighborhoods had. Findings were similar in Zenk et al.,'s (2005) study examining the accessibility of food stores by the income level and racial composition of neighborhoods. Using GIS (Geographic Information Systems) analysis of Detroit, Michigan, findings suggest that residents of high-income neighborhoods containing a high population of white residents had greater access

to supermarkets and large-chain food stores. Residents of low-income neighborhoods containing a high population of black and minority residents had greater access to small grocery stores.

Compared to suburban areas, land prices in urban areas are high and often only small plots are available. This makes it more expensive or sometimes impossible for retailers to build supermarkets in urban areas (Alwitt and Donley, 1997; Walker et al., 2010). In order to profit, supermarkets must move large quantities of goods. This proves to be difficult in urban communities where population density is high, but poverty is also high. The space issue is different in the development of supermarkets in rural areas. In this case, plenty of relatively cheap land is available but population density is low, so moving large volume of product through rural stores is problematic. The optimal combination of land, affluence, and people is found in the suburbs, and that is where the supermarkets tend to be (Grocery Store Development, 2012). Because it is difficult to successfully fit supermarkets into heavily urbanized areas, alternative must be created to ensure a healthy lifestyle for residents. However, some communities are faster than others in developing these alternatives.

Problems and Controversies

Because of the different definitions of what constitutes a food desert, it is difficult to have an accurate count of how many individuals reside in such areas (Cummins and Macintyre, 2002; Cummins, 2003; Reisig and Hobbiss, 2000; Shaw, 2006). Additionally, some people do not accept the phrasing and definitions of food deserts because they do not suggest a solution; moreover, the designation of a neighborhood as a 'food desert' creates stigma that makes these neighborhoods even less attractive (Bare, 2013). Thus, the term, 'food desert' is problematic for many advocates, one of whom notes: "A desert [meaning the type of climate] is a natural phenomenon. Lack of access to fresh, healthy food is not natural. It is not accidental" (Cook, 2010). Differential access to healthy affordable food, it is argued, is a socially constructed inequality; lack of access to affordable and healthy food in the areas where food deserts are located results from intentional decisions made by profit-maximizing businesses (Cook, 2010). The further implication is that the problem will not be solved simply by placing supermarkets in these areas; rather, local officials, service providers, and community advocates need to develop alternatives that will bring affordable and adequate food into these areas.

Residents' nutrition is often at stake because they make decisions on their food intake based on the food available to them in their neighborhood (Furey et al., 2001). In food deserts, it is typical for residents to purchase their food at the local convenience store. According to Drewnowski and Specter (2004), most food available at these locations is considered 'empty calorie' food. Hendrickson et al. (2006) state that "low-income neighborhoods have a higher concentration of fast-food restaurants and corner stores that offer prepared foods when compared to higher income communities." The American Dietetic Association believes that this kind of food insecurity can lead to negative consequences for residents, including "physical impairments, disease, psychological suffering, and sociofamilial disturbances" (Position of the American Dietetic Association, 2006). Researchers have found this to be true: individuals exposed to processed foods full of sugar and sodium experience negative health outcomes when compared to individuals who have a nutritionally balanced diet (Block and Kouba, 2006; Lewis et al., 2005; Swinburn et al., 2004). Research has found that neighborhood food environments, such as the number and types of restaurants and types of grocery stores, are associated with obesity (Powell et al., 2007b).

Another controversy surrounding food deserts is the question, 'Do they actually exist?' The idea that established the paradigm of food deserts was that people were not eating healthily because their location limited their access to full-service supermarkets. However, some studies have found that access and geography may not play a large role in healthy eating (Cummins et al., 2005; Drewnowski et al., 2010; Aggarwal et al., 2014; Wrigley et al., 2003). More specifically, Wrigley et al. (2003), Cummins et al. (2005), and Aggarwal et al. (2014) found that access to healthy foods does *not* mean that people develop healthy eating habits. Drewnowski et al. (2010) and Aggarwal et al. (2014) found by using census tract data that individuals do not necessarily shop and purchase food at supermarkets close to their residential areas. In fact, only 15% of respondents shopped within their home census tract, while others traveled nearly twice the distance to their primary food store, which was not necessarily their closest food store. The choice of supermarket was based on demographic (Aggarwal et al., 2014) and socioeconomic factors (Drewnowski et al., 2010), not convenience or location.

Possible Solutions and Alternatives

So what can help to eradicate food deserts (assuming for the moment that they do in fact exist)? While there are ideas on what could potentially be successful alternatives for food acquisition, little research has evaluated effective approaches related to food acquisition barriers (Andrews et al., 2013). In attempts to build upon the literature, Andrews et al. (2013) examined how an increase in Supplemental Nutrition Assistance Program (SNAP; aka 'food stamp') benefits levels affected SNAP redemptions at supermarkets and supercenters. More specifically, would people be more apt to travel the distance to supercenters, where prices are lower, if the SNAP program created a bigger incentive to do so? Their findings suggest that individuals would travel the distance to supercenters if the SNAP benefits were increased. However, if gas prices increased, then those who lived in 'severe' food deserts were less likely to shop at these locations (Andrews et al., 2013).

What can be changed locally? A local food system can help those who live in food deserts through Public Market Distribution, Regional (Cooperative) Food Hubs, and Community Supported Agriculture (Alternative, 2012). Public Market Distribution, meaning a resource that sells goods within local communities, serves a community a few times a week, often in the form of temporary farmer's market stands but sometimes through permanent structures. Regional (Cooperative) Food Hubs link producers to new markets. The USDA describes

a food hub as "a centrally located facility with a business management structure facilitating the aggregation, storage, processing, distribution, and/or marketing of locally/regionally produced food products" (United States Department of Agriculture, 2013). This allows for farmers to drop off their goods to distributors and customers who want to purchase locally grown food. This helps farmers because it allows their goods to be distributed across a larger area. Lastly, Community Supported Agriculture can help ameliorate food deserts. Also known as 'community gardens,' these areas of supported agriculture allow individuals to have access to fresh foods right in their neighborhood yards.

A standard definition would assist in food desert mapping and research. There is a lot of controversy surrounding not only the term, but also what qualifies as a food desert. By developing a concrete, formal definition agreed upon by all, we can map locations and count individuals that experience food deserts more accurately. Such data could then be used to educate the public and local officials on the topic of food deserts, and therefore promote plausible solutions to help reduce the food insecurities and hardship, individuals in these areas face.

This article is a revision of the previous edition article by C.M. Counihan, volume 8, pp. 5715–5719, © 2001, Elsevier Ltd.

Abstract

The anthropology of food has adopted a broad range of methodological and theoretical approaches to the study of diets, food habits, and culinary practices. Traditionally, it has examined the social, economic, and cultural differences that explain inequalities in access to food, and the problems derived from these differences. In recent years, anthropologists have begun to examine the origins and consequences of emerging culinary and gastronomic traditions linked to various forms of identity: gender, ethnic, local, regional, and national. Against this complexity and fluidity, anthropologists of food are engaging new theories to better understand contemporary problems.

Generally speaking, the anthropology of food is a broad and growing field. As the chapters in Counihan and Van Esterik (2013) illustrate, it encompasses a diversity of methodological and theoretical approaches covering different and, sometimes, opposed understandings and explanations of food and related phenomena, from multi- and interdisciplinary perspectives. Some studies privilege the biological, medical, and chemical definition of foods and taste; others privilege the cultural, symbolic, and interpretive analysis of food preferences; and still others take the preference for certain foods as a 'natural' disposition, while others focus on the political structures and relations that define who cooks and who eats what, and what is edible or unpalatable where. Also, political analyses of food and cooking have been conducted from Marxist and related political economy viewpoints, as well as from the perspective of new social movements analysis and postcolonial theory. Across most anthropological approaches to food, gender, and ethnicity are often considered important dimensions. In the past, food issues were often studied as localized phenomena, but now food and cooking have begun to be approached from broadly regional or global perspectives. In particular, the analysis of culinary practices and preferences, and the emergence of formalized cuisines, have directed the anthropologists' attention toward the relationship between food and identity from the angle of ethnic, local, regional, and global-cosmopolitan affiliations.

Prevailing Ethnographic and Anthropological Approaches

During the last two decades, the anthropology of food, and especially of food cultures and culinary practices, has come of age. In the early stages of the discipline, anthropologists looked at food as a minor feature, even if present in many dimensions of human life. For example, some anthropologists examined the part food played in religious rituals or in age or gender hierarchies in simpler, small societies. Others saw it as a product crafted from resources obtained from the immediate environment. Still others discussed food as the unprocessed product of specific environmental restrictions that shaped the ways in which a group lived.

The ethnographic record is rich in cases that illustrate how food can be used to define an array of social ties. Food offerings redefine the relationship between humans, transforming them in relatives or friends – or denying them recognition as equal human beings. Sharing food and drinks often has strong cultural meaning and symbolic significance. The anthropology of hospitality practices, for example, has demonstrated how the positions of guest and host are defined by the various manners in which food and drinks are exchanged. In general, food and drinks are ways to include the stranger into the host's society and to recreate reciprocity obligations (Ayora-Diaz, 2000). The meaning and logic of food exchange, in turn, are transferred to the domestic space. The contemporary home is a compartmentalized space; the rooms the guests are allowed to enter, along with the types of food and drinks they are offered, express the level of their affective integration into the space of the family. Food can also help maintain the affective relations between the living and the dead, as when the relatives of deceased persons set a table of his or her favorite food and drinks during the Days of the Dead in Mexico. In many places in Asia, Africa, the Mediterranean, and Latin America, food gifts maintain kinship ties among the living, and between the living and other spiritual beings, including various deities. In fact, in some cases, interrupting food offerings to deities can be seen as leading to illness and misfortune, as Laurel Kendall (1985) shows for Korean families. When families fail to perform their periodical food offerings of rice cakes to their domestic spirits they are punished with illness and other misfortunes.

Since Audrey Richards's (1939) early study on the agricultural and domestic organization of food practices and its impact on the diet of a group, anthropologists have often looked at food as a result of local production, circulation, and consumption practices; or to the different political, economic, and sociocultural reasons why food crops sometimes become an abundant or, sometimes, a scarce nutritional resource (think of the 'fast-and-feast' characterization of nomadic hunters). Against the pressing need to focus on, and find solutions to, such life-and-death issues, it is no wonder that culinary practices and the emergence of cuisines had a difficult time in gaining prominence in anthropological work.

Early in the second half of the twentieth century, Claude Levi-Strauss (1970 [1968], p. 428) suggested an ingenious approach to food codes through his now well-known 'culinary triangle.' The structure of this triangle shows at the apex the term 'raw,' which is associated with roasted; at the base of the triangle one finds on the one hand the term 'cooked' associated with smoked and, on the other, the term 'rotted' associated with boiled. Shortly before that, Mary Douglas (1984 [1966]) had examined the social meaning of food and of the organization of the meal in British society. They both paved the road for the sociocultural study of food-related practices, but, generally speaking, anthropologists were slow to take up the challenge. The recognition that the availability or shortage of foodstuffs was tied to broad social inequalities and to unequal access to the market, and that the objective quality of food is biomedically and biochemically defined, led anthropological research to study the effects of poverty on the human diet, and to medically and nutritionally defined problems, focusing on phenomena such as obesity, alcoholism, diabetes, and undernourishment – some of them defined as diseases of advanced societies, others of impoverished regions of the world. In some studies, culture was defined as the cause of ill-nutritional practices, while in others the explanation for food preferences and avoidances was found in the biological needs of human beings who would then choose their food based on rational choices (de Garine and Pollock, 1995).

Anthropologists found that the unequal access to food was tied to structural imbalances. Gender difference became an important explanatory variable in this regard (Counihan and Kaplan, 1998). The focus on gender, food, and cooking was then inevitable: With a few exceptions, in most societies anthropologists found a tendency toward the subordination of women to men, which led to the confinement of women to everyday chores, including cooking. Although cooking is necessary for the biological reproduction of the species, women's cooking, even in the so-called 'advanced' societies, was trivialized as an everyday chore performed within the private domain of the kitchen. Men, on the other hand, directed and controlled the cooking and display of food in public celebrations. In North Atlantic cultures, the professionalization of cooking became a male-dominated field, and women had to learn from male chefs the 'correct' cooking procedures. These inequalities, which led anthropologists to see food in its more public roles as an economic and symbolic good to be exchanged in public rituals meant to cement broad social ties, is now compensated by explorations of the oral and written strategies displayed by women to transmit cooking knowledge from one generation to another, by the analysis of women's sociality during cooking events, and by studies of breast feeding, diets, and of women's role as the care givers of the family. In any case, anthropologists now see the explanatory power of gender as necessarily entwined with other dimensions; looking at the convergence of gender and poverty one can better understand the sociocultural reasons why the economic organization of food production and distribution takes certain shapes. Relating gender to food can help us understand why and how in some societies women may be excluded from certain productive activities, while in others they are assigned the responsibility over their production and circulation.

Gendered food practices can become tightly intertwined with ethnicity. Thus, for example, in central Mexico, women become responsible for both nurturing the family and for maintaining the cultural ties between central Mexican indigenous groups and their past. In some groups, women are assigned the task to watch over the maintenance of religious values and practices, and food plays a very important symbolic part, sometimes as offerings to gods, saints, or ancestors and sometimes as the vehicle of spiritual powers, but in every case as a means to found gender roles, to cement family ties, and to preserve the social status quo that give ethnicity its naturalized qualities. Thus, in contemporary anthropology, the analysis of gender and food becomes inseparable from the study and analysis of power relations among ethnic groups. However, even beyond gender, food preferences can become tied, for different reasons, to ethnic identities. A common practice to draw the boundary between a group and another lies in invidious differences of what each groups considers edible, or in the foods they prefer. Mock names used to refer to members of a different society often tend to ridicule or to signal their group preferences as contemptible: 'Frogs' and 'Krauts' are broadly recognizable as terms intending to ridicule French and German people. In Mexico, outside Mexico City, 'chilangada' is often used to despise central Mexican food preferences and cooking. The author has also found, in Chiapas, Mexico, that Mayans who speak, for example, Tzeltal, sometimes equate the food of the Tzotzil-speaking people with animal feed and claim they have never eaten some foods favored by the Tzotzil-speaking Mayas. Also, anthropologists have also looked at the ways in which foods perceived as 'ethnic' may become acceptable to members of dominant society (Gabaccia, 1998). For example, Chinese, Italian, and Mexican foods were tied in the US imagination to low-class immigrants and took some time in becoming an everyday choice in most cities and towns of the country.

Anthropologists have also taken an interest in the ways in which food can be a vehicle or an instrument in religious practices and discourses, or both. From Mary Douglas's *Purity and Danger* (1984 [1966]) to more recent work, anthropologists of different persuasions have debated the meaning of food taboos and preferences as informed by religious worldviews. Different religions have their own understanding of ritual cleanliness and pollution and their choice of food is frequently informed by those religious definitions of the edible and inedible. In places where several religions coexist, anthropologists have taken advantage of this plurality of worldviews to look at the intersection of religion and, according to the case, more or less rigid hierarchical social structures, examining some of the ways in which food articulates discourses and exclusionary practices. A related approach has focused on popular beliefs and discourses, legends, and puns that highlight the cultural importance of foodstuffs in articulating religious differences, local identities, gender relations, and various mystical/mythical attributions, as seen in the work of Fabre-Vassa (1997 [1994]). She describes and discusses the stories surrounding the Jews and their imagined relations with pigs in French rural society, the ways in which the pig became a marker of cultural difference and distance, and how it turned into a justification for the social discrimination and exclusion of Jews in Catholic France.

Globalization and the Anthropology of Food

The development of critical and reflexive anthropology led anthropologists to understand local practices and identities as tied to broader processes. Regarding food, globalization theories and analyses helped to take into account different levels of complexity that went simply unnoticed in previous work. The seminal work by Sidney Mintz (1985), *Sweetness and Power*, demonstrated the necessity for anthropologists to take a deeper historical perspective to understand contemporary food production and consumption practices. These are practices and processes that irremediably tie different places of the world to, and different social classes within, any single society. Mintz unveiled the historical reasons that transformed sugar from a luxury commodity proper of the aristocracy into an everyday good of the working classes in England, while at the same time disclosing the shifting power position of different European countries and the sugar-producing Caribbean region over time. His work inspired further research into the differential inscription of edible commodities in the global market. Nonetheless, other theories have also informed anthropologists' study of local–global interactions. For example, Gabriela Vargas-Cetina (2000) has described and analyzed how a local Sardinian product, *pecorino* cheese, was the result of the appropriation of nonlocal technologies and techniques, and the process whereby it became a valued global commodity consumed elsewhere, from the times of the Roman empire into the present. Other products have had rather uncertain fates. Some agricultural products traveled from one place of the world to another, first despised by the mass and elite consumers of Europe, but later they became accepted, sometimes as essential ingredients of national foods. In the opposite direction, colonizers despised local foods and enforced the consumption of imported European and Asian products in the American continent. It is known that in Europe tomatoes were initially thought to be toxic, but later they were integrated into European high cuisines. Chili peppers originated in the American continent, but they are today essential ingredients of European, Asian, African, and other cuisines. In some societies, a product may be valued by a segment of the population, while another social segment despises it as animal fodder – or food for the poor.

In recent times, industrially, mass-produced goods have become prime examples of the homogenizing process of globalization. However, true to the social sciences' recent interest in the processes through which the global becomes localized and the local globalized, many studies have shown the diversity and heterogeneity of outcomes resulting from the local appropriation, adaptation, and resignification of global commodities. Robert Foster (2008), for example, has followed one of the paradigmatic industrial manufactured goods, cola drinks, in their commercial displacements and described the dissimilar forms of appropriation and resignification that this commodity undergoes in its travel from the United States to Papua New Guinea. Foster traces the material and symbolic transformations of these drinks, the images that become associated with it during marketing campaigns (e.g., modernity and youth), and the different understanding that people have of the same images both in the United States and in Papua New Guinea. His study illustrates how local adaptations and appropriations explain contrasting codes that signify the use of a product and its consumers' self-representations.

In the contemporary context of globalization, not only single commodities, such as ingredients, travel. Through a long history of intercultural and international contacts, different food traditions have been adapted to the new environment and food markets in which large numbers of migrants found themselves. Economic migrants, diasporic subjects, political refugees, and exiles develop different relations to the food of the homeland. Despite fears of global homogenization, the anthropological literature, perhaps because of its privileged focus on local practices and meanings, has continuously shown that foods are regularly appropriated and resignified, even if this local redefinition leads to attempts to defend its purity or authenticity. Indentured workers, slaves, economic migrants, refugees, exiles, and diaspora subjects, despite the suffering involved in their displacement, or sometimes because of it, seek to replicate and transfer their food taste and preferences to their new homes. So, they adapt and transform their homeland food traditions to the ingredients and environment they moved into. Often, cooking is an occupation that can help a group to physically survive. At the same time, migrants replicate and adapt the foods of their homelands and globalize their local cuisines. Chinese, Indian, Japanese, Korean, Thai, Vietnamese, Finnish, German, Italian, Spanish, Argentinean, Brazilian, and Mexican (to name those numerically important groups of migrants) carry and adapt their culinary traditions to new environments. Less concerned with 'authenticity,' these groups seek to negotiate the meaning and importance of their culture in different host societies. They are more willing to transform their foods both to satisfy the migrants' nostalgia for the homeland, and the host's acceptance of their food ways as manifestation of cultural 'authenticity.' Migrant foods and populations are often constrained to adapt the food to the ingredients they find in their new homes, and to the taste preference of the members of the host societies who also become consumers of imported foods. So, not only the social demarcation of identity, but also the necessarily shifting reproduction of home cultures from elsewhere, is expressed through food and dietary adaptations.

Another aspect of the globalization of food relates to the expansion of North Atlantic food businesses. Hamburgers, hotdogs, and other fast food sometimes become associated with images of youth and freedom, and temporarily displace local foods in the preference of Asian, European, African, and Latin American consumers. Anthropologists have looked at how these newly introduced food products can contribute to changes in local food habits and dislocating age and gender hierarchies, as when McDonald's in Asia helped reverse the symbolic place of children in Asian families, which were increasingly focused on fulfilling the every wish of small infants (Watson, 1997).

Very few anthropologists have looked into the globalization of European cuisines, leaving the field mainly to historians and scholars from cultural studies. Instead, they have chosen to study the ways in which cooking may become recognized as a particular set of local practices. Trubeck (2008), for example, looked at French cuisine from a historical angle, and showed the influence of chefs and restaurants in establishing French

gastronomy as the universal gold standard to measure all other cuisines. She documents how, after the French Revolution, chefs lost their place in the homes of the aristocracy and opened restaurants in France and in many other countries, and on their own authority established the principles of French cooking as universally applicable rules. Today, one can see that Italian and Spanish traditions have followed suit, putting efforts into establishing theirs as national 'high' cuisines. Similarly, as cultural brokers from different local societies, cooks seek to reposition their ethnic or regional foods as equal to established high cuisines.

Anthropology, Modernity, and Food

Modernity is today, like 'tradition' was in the past, a primary focus of anthropological studies. No longer constrained to study local, bounded communities, anthropologists are looking at global–local and translocal relations, and at the cultural consequences of late capitalism, in particular, to the way in which emerging cultural formations – be they called 'modernity' or 'postmodernity' – create new meanings for the different types of food that we consume, the culinary practices that produce 'authentic' and hybrid cuisines, and the ways in which food becomes tied to fluid, changing social structures.

Contemporary tourism has played a significant role in creating a demand for authentic, local cuisines. When migrants moved into new countries, they produced meals for themselves, to satisfy their longing for the homeland. However, gradually, consumers from the host society became acquainted with immigrants' culinary traditions and accepted local adaptation to their foods. As travel became more accessible for the consumers from affluent societies, so grew the desire for more 'authentic' renditions of ethnic and national foods. Many travelers favored regional foods as mementos to take back home from a trip. However, as several authors in Lucy Long's volume (2004) suggest, tourists and foods providers have been forced to negotiate their understanding of authenticity, and cooks are often consciously seeking to satisfy both the tourists' and their own imagination of what they perceive to be the longing for exoticism attracting visitors in tourist destinations. Both within the United States and elsewhere in the world, local people recognize the variations in taste displayed by tourists and sometimes they modify their foods to fit the visitors palate, or like in Sardinia, shepherds stage 'traditionally authentic' cooking in the desolate landscape of the mountain plateaus of the island, seeking to satisfy the ecotourist imagination of those visiting the region.

Still, in the contemporary world, the search for the authentic and the pure is not restricted to the tourist imagination. Distrustful of the food fed by corporations, by the growing perception of risk associated with epizootic crises such as the aviary flu, bovine spongiform encephalopathy, food and mouth disease, and the growing production of genetically modified organisms (GMOs) and transgenic foods, as well as the bacterial contamination of vegetables and other produce, consumers are developing a strong resistance to industrially processed and packaged foodstuffs (Lien and Nerlich, 2004). In response, different movements have emerged that take a philosophically and morally critical view of the dominant contemporary food-provisioning system, and demand for alternatives. The Slow Food, and the 'Going Local' movements are models for a range of responses articulated by consumers who increasingly and in growing numbers come to value locally produced foodstuffs, organic food, free-range animals, and food free of transgenic manipulation and GMOs, valuing 'natural' over industrially produced, 'artificial' foods. Today, many consumers attribute their favored foods a better taste, a higher cultural value related to artisanal production, and a heightened purity and authenticity deriving from organic agriculture. Although many of these movements originated and gained strength in Europe and North America, the values and worldview they uphold are now changing the perception of food, and its political–economic and moral values, everywhere else. Hence, consumers recognize a higher value in wine, cheeses, vegetables, and animal meats for which producers can guarantee and certify as local, organic, free-range, artisanal, free of chemicals, antibiotics, and hormones, that is, free of artificial manipulation. These values have driven in recent years the commercial success of organic food supermarkets in North America and Europe, and contributed to the resurgence of farmers' markets everywhere.

National and Regional Cuisines and Identities

As anthropologists have focused their attention on the relationship between food and identity, it has become increasingly evident that just as gender, religious, and ethnic identities are entwined with the meaning of foods, and culinary practices, so are national and regional identities. Since rice, corn, and wheat constitute the basic, everyday ingredient in the diet of different groups, they tend to be equated with life itself and are often attributed great religious, social, political, and cultural significance. The culinary preference for one among the different varieties of rice grown in different Asian countries is sufficient to found national and moral differences between one group and another. In Mesoamerica, corn has been taken as the life-giving ingredient. One of the most religiously important texts, the *Popol Vuh*, defines corn as the substance from which humans were made during the last creation of the world. In Europe and the Middle East, wheat receives religious, mystical, symbolic significance, and different stories affirm its divine origin, sometimes even granting a higher status to the people who consume them. Anthropologists have argued, on these grounds, that these food staples become intimately tied to the group's cultural notion of self in these societies and constitute the symbolic core of their ethnic identities. This notion of ethnicity has been extended to argue, in some instances, that a national cuisine, such as the Mexican, is tied to a single ethnic indigenous society encompassed by the nation-state. Cultural elites in Mexico have promoted the view that there is a single Mexican national cuisine, which is based on pre-Colombian ingredients such as corn, beans, tomatoes, squash, and chili peppers (Ayora-Diaz, 2012a).

The relationship between food and ethnic, regional, and national identities is a very complex one. One artifact of the invention of the modern nation-state is the need to visualize the coextensiveness of the political and cultural forms. With the exception of a few societies, most political regions that emerged

as nation-states encompassed a diversity of groups that had developed their own cultural practices, including those pertaining to the realm of the kitchen. England, France, Germany, Italy, and Spain, countries in which the modern nation-state was conceived, encompassed different regions where different produce and different cooking styles had developed. The emergence of national cuisines partially concealed, sometimes on purpose, the regional diversity of each country. It is only by looking at the history of a nation-state that one can understand, anthropologically and ethnographically, the emotions and identities associated sometimes with a single ingredient, and sometimes with full-fledged gastronomic traditions.

Arjun Appadurai's (1988) groundbreaking paper led anthropologists' attention to the study of the ways in which a cuisine could be used to stand for the nation. Appadurai explains the growth of the printing industry of cookbooks of Indian cuisine in the context of the colonial relations between India and England, and later the process of decolonization. Despite the great diversity of worldviews and related food preferences and proscriptions, members of the Indian upper castes, at home and abroad, collected recipes into cookbooks, creating the illusion of a national cuisine. Thus, anthropologists have been studying how, from a minor literary genre, cookbooks around the world were turned into the foundations of gender, ethnic, regional, and national identities.

The preference for ingredients, culinary techniques, and technologies are generally based on discursive references to authenticity, but anthropologists increasingly understand national cuisines as modern inventions. The creators of national cuisines have been forced to negotiate between local and imported culinary practices, and most national cuisines, as those exemplified by anthropological studies on French, Japanese, Chinese, Italian, Belizean, Brazilian, and Mexican cuisines, are the product of local–global connections that have stimulated the appropriation and adaptation of ingredients and culinary techniques to the local culinary aesthetic code. People and their cuisines travel, and in recent decades gastronomic tourism has become an important stimulus in the invention and affirmation of national cuisines, as service providers vie for a position of privilege within the market of ethnic and national foods. In the cases listed, these adaptations have led to the creation of something different from the cuisines of origin, and attributed to the ingenuity of national cooks. In all these cases, anthropologists have shown that cooks/chefs, restaurants, and cookbooks have played an important part in establishing national gastronomic traditions.

Regional cuisines, on the other hand, have received a different treatment. In some cases, local pride and identity have been described as tied to a single product of the land or water: garlic, camembert cheese, wine grapes, champagne, caviar, and crayfish, to mention just a few, are taken as markers of the land and the people who produce them, and as foundations of a local or regional identity. In other cases, in Europe, Latin America, and the United States, anthropologists have taken different regions within a country as characterized and circumscribed by a particular bioecological environment and inhabited by people with distinct cultural backgrounds. That is, some regions have become the chosen territory for descendants of African slaves, of indigenous people, mestizos, or Italians, French, Spaniards, Germans, Russians, Lithuanians, Chinese, Japanese, Koreans, Algerians, Iranians, Indonesians, etc., and understand their food preferences as supported by a strong regional identity (Counihan and Kaplan, 1998; Counihan and Van Esterik, 2013; Long, 2009; Pazos Barrera, 2010). However, in other instances, local groups with a history of secessionism or with strong regional identities, use food as an instrument to distinguish their taste, moral worldview, and social status vis-à-vis strong central governments (as it is the case, for example, of the Basques and Catalans in Spain, of Sardinians in Italy, Corsicans in France, and Yucatecans in Mexico) (see Ayora-Diaz, 2012a, b). These cases allow us to see how, in its increasing diversity, the anthropology of food is finally becoming a major subfield of cultural anthropology.

Future Directions in the Anthropology of Food

The diversity of topics and problems encompassed by the anthropology of food provide a wide field in which anthropological theories and concepts, and field methods can be tried to enrich our understanding of the contemporary world. Since multiple aspects of everyday life, in rural and urban societies, will continue to inspire anthropological studies, practitioners of the field can broaden their multidisciplinary and interdisciplinary approaches to the study of changing diets, food habits, food-related bodily images, gender and structural inequalities, the effects of other organisms on the health of groups and individuals, and the advantages and nutritional properties of a vast array of foodstuffs that contemporary agricultural and industrial production practices allow.

Anthropologists are also finding a wealth of issues to study and analyze regarding the different social movements, their ideologies, moral understandings, political, and economic motivations around issues such as GMOs and transgenic foods in the contemporary diet. Also, worldwide growing movements such as Slow Food, 'Going Local,' permaculture, and City Gardens deserve closer ethnographic attention. Food corporations compete with these movements for the consumers' favor and both groups unfold commercial, political, and moral practices and discourses that can be productively analyzed from an anthropological perspective.

Also, the continuous displacement of groups of people from one place of the world to another, forced by war, political, economic, religious, and other reasons, generates multicultural contexts in which members from different cultures must negotiate the meaning of their own culinary practices. Tourism, another form of mass displacement of people, fosters the emergence of ethnic and national cuisines that at the same time procure a niche in the global market of edible commodities and constitute the basis for affirming local, ethnic, regional, and national identities. In all these cases, the contemporary world imposes on anthropology the need to take into account the blurring of cultural boundaries; the fluidity and friction in the movements of people, ideas, commodities, and culinary codes; the instability of contemporary social and cultural formations; and the reactive attempts to affirm local against foreign foods. These different issues demand the creative appropriations of new concepts and theories, and post-structural and postcolonial theories could help explain many of

these transformations as well as emerging food and culinary practices and ideologies. These theoretical approaches are beginning to supplement other, well-established ones, such as political economy theory, the different types of structuralism, cultural relativism and neopositivism. It is possible to say that in the near future, food anthropologists will continue to engage in different manners with the complexity of today's contemporary culinary and dietary issues, and will develop increasing ties with other already established disciplines surrounding food problems.

Abstract

Human food choice is influenced by biological, psychological, and cultural factors. Because humans are food generalists, and because the food environment in the first world is so different from the ancestral human environment, innate predispositions play a minimal role. Humans principally learn to eat and like certain foods, and avoid others, with traditions being the main influence. Preferences can be based on the instrumental consequences of eating (e.g., nutritive or toxic properties of foods) or on liking for the taste. Mere exposure, pairing of foods with positive or negative consequences, or a variety of social influences foster liking or disliking. In the extreme, these and other forces turn an innate dislike, as for chili pepper, into a strong liking. Surprisingly, family influences on food preferences are very modest. Food functions in many ways, for example, as a social or moral entity; food preferences are therefore influenced by things such as the nature or origin of a food, and moral/religious attitudes, such as concerns about killing animals. In the developed world, with a surplus amount of foods, a wide variety of foods, and the conquest of most infectious diseases, concerns about food have focused more on obesity and the long-term consequences of diet. As a result, the pleasures of eating, especially in the United States, have become tempered by a fear of fat and food. The situation and person are both major determinants of choice, including the social setting, the time of day (e.g., breakfast vs dinner), eating at home or away from home, and the stage of life, from infancy to old age.

Introduction

Food and food choice constitute a major part of waking human activity, and, in the developing world, the major expense. Furthermore, food choice may be the single most important selective force in animal evolution, as suggested by the fact that many animal groups are named for their food habits (e.g., carnivores, insectivores). In human evolution, adaptations to obtaining large animal foods played a significant role in the evolution of the human brain and human social organization. Early advances in food procurement, agriculture and domestication, set the stage for major advances in technology, and the development of urban centers. Food has served as a foundation for the cultural evolution of nonfood systems, such as religion, ritual, and social exchange, through the cultural evolutionary process of preadaptation. Through many elaborations and the development of distinctive cuisines, food has become an important component of group identity, and a major source of pleasure, which sometimes can be classified as aesthetic. Thus, an understanding of human relationships to food promises to both enlighten a major area of human concern, and to enlighten other areas. The elaboration of eating into a refined and civilized activity in Western culture is beautifully described in Leon Kass' (1994) book, *The Hungry Soul*.

The Basic Relationship between Humans and Their Food

For any person, the world can be divided into the self and everything else. Eating involves taking matter from outside the self and putting it inside the self. This is a very intimate act. It is not surprising that people feel strongly about what they eat. The costs in terms of toxins, microorganisms, or imbalanced nutrients are high, but the benefits are even higher: survival is at stake.

Humans (and rats and cockroaches) are food generalists. They eat a wide range of foods; virtually anything that can fit into the mouth is potential food. Generalists have few innate determinants of food choice, simply because it is not easy to predict the nutritive and toxic properties of a potential food on sensory grounds. There are only a few documented innate biases in human (and rat) food choice. First, there are innate predispositions to like or dislike certain tastes. There is an innate preference for sweet tastes, which, in nature, are predictive of calorie sources. The long history of sweetness in human culture, from fruit preferences to cultivation of fruits, to extraction of sugar from fruits, to colonization of the Americas partly to get a source of sugar, to the development of sugar substitutes, is all driven by the innate liking for sweet tastes (sugar). There is an innate tendency to dislike bitter tastes, and there are probably innate predispositions to reject very strong tastes including oral irritation (as from peppers) and to like fatty textures. Second, there is a suspicion about trying new foods called neophobia (on account of potential toxicity), but also a conflicting interest in them (on account of their potential as a new nutrient source). This has been described as the generalist's (omnivore's) dilemma. Third, there is a special learning mechanism, which allows learning about the consequences of ingestion, even when these may occur hours after ingestion. Fourth, there are a few specific internal states, which seem to signal the need for specific nutrients. Examples are thirst promoting procurement of water and hunger, promoting procurement of sources of energy. There may be a specific internal signal associated with sodium deficiency.

Humans are mammals, and hence have a unique first food, milk. Humans and other mammalian generalists make a transition from this single food to a very wide range of foods. This transition is made under the guidance of parents and other caretakers, and usually consists of a scheduled and graduated introduction of new foods, accompanied by mental maturation of the child and increased ability to chew food. For all mammal species except a subset of modern humans, full digestion and utilization of milk is limited to infancy. The development of dairying afforded the opportunity for humans to exploit milk and its products as adult foods.

Determinants of Human Food Choice

For humans, food choice is accounted for by some combination of biological, psychological, and cultural factors. The role of biological factors is limited for two reasons. One, as discussed above, is the human generalist orientation to food. Second, the modern developed culture world presents a food world to its members, which is vastly different from the ancestral world in which the biological predispositions evolved. A shortage of food has been replaced by a surplus of food. A modest range of natural, local foods has been replaced by an enormous range of foods, representing most of the world's cuisines at a neighborhood supermarket. 'Super foods' like chocolate with an extraordinary appeal to our innate liking for sweet and fatty tastes have been invented and widely distributed. Food choice, for some in the developed world, represents concerns about child labor, species at risk, and the appropriation of much of the food system by large corporations. Many of these themes are well expressed in Michael Pollan's (2006) book, *The Omnivore's Dilemma*. A major risk of food poisoning from toxins and microorganisms has been sharply reduced; the longer lifetime that has resulted from this and other medical advances establishes a new and more subtle link between dietary patterns over decades and degenerative diseases. Direct experience of food and the consequences of ingestion have been largely replaced by exposure through the media, schools, and other social contacts. Massive amounts of information (some accurate) relating dietary pattern to wellness and disease is widely disseminated. And finally, the linkage between energy expenditure and finding food (or finding anything else) has been almost eliminated. Thus, while the ancestral food environment focused on shortage and short-term consequences of eating, the modern environment stresses overabundance and long-term consequences. However, we must remember that more than 80% of people on Earth are not in the developed world. For them, getting enough food, both calories and nutrients, remains a major concern. Most of their food choices are dictated by strong culinary traditions and economic constraints. These people are not yet inundated by an abundance of different foods, although colas and candies and fast foods have already entered their lives. As globalization continues, and agriculture and distribution systems improve, more and more of the world will face the inversions of our ancestral environment. Culture is the most powerful determinant of human food choice. More can be learned about an individual's food attitudes and preferences from his or her cultural identity than from any other single piece of information. Food choice is highly constrained by availability and cost, and both of these are largely determined by culture, as well as local climate. Exposure to a food is a necessary, and sometimes sufficient, condition to produce a liking for a food, so that cost and availability indirectly but powerfully influence the development of food preferences.

Cost and availability aside, human preferences and food attitudes can be framed by a psychological (as opposed to nutritional) taxonomy of foods. There may be three types of reasons for rejecting or accepting a food: *sensory affective*, that is, feelings (pleasure or displeasure) based on the sensory experience (largely taste and smell); *anticipated consequences*, what the expected consequences are of eating a food; and *ideational*, what is known about a food (e.g., where it comes from, what the nature of it is).

Food rejections can be understood in terms of the selection and interplay of these reasons. One category of rejections is called *distaste*. These are entities rejected because of negative sensory affective properties, such as lima beans, broccoli, beer, or chili pepper, for those who find these foods distasteful. A second category is *danger*. These are things rejected primarily because they are believed to be harmful, because of acute or long-term consequences. The emotion of fear is often associated with their consumption. A third category of rejected things – the largest category – is called *inappropriate*. These are things that the culture labels as inedible, such as pencils, grass, paper, or cloth. They might taste good, and might be harmless, but they are rejected for ideational reasons. The fourth category is *disgust*. Disgusting food rejection is also based on ideational, culturally transmitted information, but unlike inappropriates, there is a strong belief that disgusts taste bad and are harmful. Unlike the affectively neutral response to inappropriates, the response to disgusts is strongly negative and emotional. Disgust is the most powerful reaction people have toward food. Disgusting entities are so powerful that if they touch an otherwise acceptable food, they render it undesirable, disgusting, and inedible (the principle of contamination or contagion).

On the positive side, there are four comparable categories. Good taste (acceptance principally because of sensory properties), beneficial (acceptance largely because of consequences), appropriate (acceptance because it is culturally designated as food, or food for a particular occasion), and transvalued (food enchanced because of its prior history). The transvalued category is much weaker and smaller than the disgust category, in most cultures. In Hindu India, food that has been 'shared' with the Gods (via donation to the priests in the temple, and then returned, in part), called 'prasad,' is an example of transvaluation.

The Acquisition of Food Preferences

For newborn infants, the only functioning categories are good taste (e.g., sweet) and distaste (e.g., bitter). Generally, infants will place in their mouth anything that might fit in, including feces and potentially toxic foods. Gradually, they acquire more distastes and good tastes, and learn about dangerous and beneficial foods. Disgust appears later. The full adult categorization is in place by roughly 5–8 years of age.

Most is known about the distinction between distaste and danger. When ingestion of a food is followed by nausea, it tends to become disliked, that is a distaste. However, if ingestion of a food is followed by most other negative symptoms (e.g., lower gut pain, skin rash, respiratory distress), the food typically becomes a danger. With respect to affect and emotion, it is notable that dislikes (distastes) and dangers have very different properties, although the outcome (rejection) is the same. The nausea-based acquired distaste (often called a conditioned taste aversion), unlike dangers, is not based on a legitimate sense of danger. Even if a person knows that the nausea/upper gastrointestinal illness was not produced by the food, the aversion remains.

The acquisition of good tastes is more complex and less understood. Mere exposure to a food, in itself, often seems sufficient to produce an acquired like. In addition, the association of a food with an already positive event (an already liked food mixed with it, positive regard by a respected person, a pleasant environment, nutritive postingestional consequences), by a process called evaluative conditioning, can lead to acquired likes (or acquired dislikes, if the paired events are negative, as in conditioned taste aversions). Indications of liking by a significant other (peer, older child, teacher, parent) may cause acquisition of liking. The process at work here is not understood. Efforts by adults to promote liking by emphasizing the beneficial consequences (better health, a specific reward for eating) seem to block the acquisition of liking for the food. When a child observes respected others enjoying a food, this promotes liking; when she is rewarded for consuming it, this seems to block the acquisition of liking.

The acquisition of knowledge of appropriate and inappropriate foods seems to be largely cognitive and affect free. The affect-laden acquisition of disgust contrasts with this, and may originate with the process of toilet training, which produces the universal disgust, feces. Some communication of affect (facial and other) is almost certainly involved, but there are also important cognitive aspects; it is the nature of the foods and their history that is central to this category.

Individuals in specific cultures develop likings (the good taste category) for some foods that are innately unpalatable (e.g., bitter, very strong tasting, irritating). Innately unpalatable foods are typically among the favorite foods: chili pepper, black pepper, ginger and other irritant spices, coffee, bitter chocolate, tobacco, alcohol, burnt foods, and highly salted foods. Such reversals of innate aversions are common in humans, and absent or rare in animals. We do not know how these preference reversals occur. In part, it may be through the same processes that produce normal likes: mere exposure, evaluative conditioning, and social approval. But there may also be special mechanisms that are involved in preference reversals. One possible mechanism places liking for innately unpalatable foods in the same category as thrill-seeking activities such as roller coaster riding. That is, humans get pleasure out of situations in which innate aversions or fears are stimulated, but in which they realize that there is no real danger. Roller coasters are safe, and so is chili pepper. This may be the case of pleasure derived from 'mind-over-matter.'

Family Influences and the Family Paradox

There are strong arguments for high parent–child resemblance in food habits. There is the common genetic heritage (including genetically based bitter sensitivity), mother's milk transmits some of the flavors of the mother's diet, parents control access (and hence exposure) to foods, and the principal affective signals about foods in early life come from the parents. Yet parent–child correlations in liking for foods are very low, in the range of 0–0.3, in comparison to parent–child correlations in values (such as attitudes to abortion). These low parent–child correlations appear whether the children studied are 4 year olds or college students. This family paradox cannot presently be explained. Of course, our first food, milk, was not available as a food postweaning in our ancestral environment, so from an evolutionary perspective, we should not develop strong lifelong attachments to our first food. Although all experiences with food, from the womb, onward have some influence on adult preferences, there is no reason to privilege the first 6 years of life. There is reason to believe that peer influence is very important, throughout the school years, although this influence has received relatively little attention.

Preferences and Values: Moralization and Vegetarianism

Selecting and consuming a food has social and moral implications, as well as physiological and sensory consequences. The source of a food (e.g., who prepared it, animal or vegetable origin) can powerfully influence acceptance. Particular food or food product boycotts in recent decades testify to this fact. Hindu Indian concerns about food fall largely within the moral domain. In the United States, there is a long history linking particular foods with the good life or immorality. Through the process of moralization, choice of a particular food may move from the domain of preferences to the domain of values. This has clearly happened with cigarette smoking in the United States. For some vegetarians, eating of animals is an immoral act. When ingestion of a food (including alcohol) becomes moralized, censure of consumers becomes licensed and governments and institutions may take limiting or prohibiting actions.

The Nature and Context of Food Choice

Food choices are sometime made on cognitive/rational grounds, whereas at other times the choice is made more rapidly and intuitively. First exposures to a food (at the point of purchase or ingestion) are more likely to engage rational concerns, whereas subsequent choices of the same food tend to be made in a more automatic, habitual manner. Repeated consumption of the same food on different occasions is likely to lead to increased preference, perhaps because of mere exposure, but repeated consumption over a short period of time can lead to boredom and reduced pleasure (called sensory-specific satiety). Food choices are often made well in advance of actual consumption, as in ordering in restaurants or purchase in a food market. Under the latter conditions, important determinants include branding and salience of the location of foods in the food display. The individual context is also important, including the time of day (breakfast vs dinner foods), the time of year and special annual celebrations like the American Thanksgiving, and stage of life, from infancy to old age.

Across the life course, one goes from intake determined largely by others in infancy to more and more agency in food choice with age, until older ages when the power of choice may become more circumscribed. Important areas of recent concern include social class and gender as determinants of food choice, and cultural differences in concern about genetically modified foods. Finally, the social context of eating affects both the amount eaten and food choice. Social comparison and social

norms have substantial effects. There are intense and often very pleasant social interactions, sometimes called commensality, that take place during meals. In short, understanding a single food choice engages a wide range of influences.

Food, Fear, and Pleasure: Cultural Perspectives

In the nonhuman animal world, and among traditional humans, food is basically a source of pleasure. Even in the developed world, cost and availability aside, the principal factor influencing food choice is taste, that is to say, pleasure, although convenience, health, and processing history of a food are also important determinants. However, with the major changes in the human environment in the developed world, obesity and the consequences of long-term exposure to particular diets have become more salient. As a result, the earlier simple pleasure of eating has become, for many people, an ambivalence, or even an outright fear. This is most well developed in American women, who often fear food as much as they savor it. In some, there is now embarrassment and guilt about consuming high-fat foods, great concern about thinness, and great concern about the healthfulness of every bite of food. This is not a necessary consequence of the modern environment, since in France, the pleasures of eating still dominate.

Abstract

The intensified intervention of people with the lives of plants and animals that ultimately led to their domestication is arguably the most important cultural revolution since the beginning of the Upper Paleolithic (the appearance of modern human behavior *c.*120 000–50 000 BP). Food production is considered here to be synonymous with agriculture. Food production references a range of adaptations from pastoralism to low through higher degrees of dependence on domesticated plants and animals. Archaeological evidence indicates that food production and agriculture developed independently in more than 10 locations around the globe during the Holocene. The first evidence of ecological management that leads to agriculture dates to between 13 000 and 10 000 years ago.

The Origins of Food Production in World Areas

Systematic research on the origins of food production demonstrates that independent origins were widespread around the globe. The main exceptions are Australia and Arctic regions where indigenous plant and animal domestication did not occur. Yet even in Australia aboriginal peoples developed sophisticated plant and animal management strategies, usually focused around burning. Human-set fires in the Western Desert have been crucial in maintaining biodiversity and habitat mosaics and were an important aspect of landscape management (Bird et al., 2005). Interdisciplinary archaeological projects are recovering evidence for early food production in Africa, Southwest, South and East Asia, New Guinea, and the Americas. A brief global survey follows.

The Origins of Food Production in Southwestern Asia

The first domesticated food plants were a tree fruit (the fig), large-grained grasses (rye, wheat, barley), and legumes (lentils, peas, vetches) (Zeder, 2011). The earliest regular use of these crops dates to 11 000–10 000 BP. Tilling the soil and tending plants may have begun even earlier, by 13 000 BP. Evidence of breeding control of animals (goats and sheep) also comes from roughly the same period, 12 000–11 500 BP. Daniel Zohary (1996) thinks that most of the founder crops (wheat, barley, and legumes) were domesticated only once or twice, and then spread both east and west. The first domesticated animals were sheep and goats at, for example, Nevali Cori at the headwaters of the Euphrates River (10 500–10 200 BP); pigs and cattle appear to have been domesticated by 10 300 BP and 9000 BP, respectively.

An extraordinary discovery in the late 1990s exposed a 20 000-year-old occupation in the shallow waters near the shores of Lake Galilee (Kislev et al., 1992; Weiss et al., 2008). Not only were small, fragile houses evidenced in the well-preserved remains at Ohalo but also were the remnants of gathering and hunting. Particularly informative were the vast array of grass seeds and tree fruits the site's inhabitants collected. The grasses included the wild ancestors of plants that, over 10 000 years later, would be domesticated. As time passed, the descendants of Ohalo's inhabitants began to focus on a narrower range of grasses and turned their attention to growing barley and wheat. Gathering evidence from between 12 000 and 8000 years ago tells us that there were distinctive pathways to food production not only in the hilly flanks of the Zagros to the east but also within the Levant as well (Goring-Morris and Belfer-Cohen, 2011). These distinctive pathways seem to correlate with the mosaic of habitats and climates that characterized the Levant in the early Holocene. Ecotones within this mosaic are sensitive to both short-term and long-term climatic fluctuations.

The Natufian culture (15 000–11 600 BP) is particularly relevant because it was at the end of this period, and the beginning of the subsequent Pre-Pottery Neolithic (PPN; 11 600–8400 BP) that populations began to invest in food production. The Natufian, or Late Epipaleolithic, is characterized by a significant increase in community size, marked sedentism, and much longer duration of settlements than in the preceding Upper Paleolithic. Although it is tempting to refer to the Natufian as transitional between the Upper Paleolithic and Neolithic, they were not; rather, their lifeway represented a long-lived adaptation in the region marked by increased packing of settlements and strong territoriality marked by local variations in material culture (Goring-Morris and Belfer-Cohen, 2011). Unfortunately, few plant remains have been found from Natufian and early PPN occupations although animal bones are well represented. Hunting intensified with people focusing on gazelle (Legge and Rowley-Conwy, 1987). The first hint that plants were being domesticated come from the PPNA occupation (11 600–10 500 BP) of the Abu Hureyra and Gigal sites. Seedless fig that requires human intervention to reproduce is the earliest evidence (11 400–11 200 BP) of a domesticated plant in SW Asia (Kislev et al., 2006). Large, plump rye grains dating to *c.*11 000 BP are more like domesticated than wild rye (Moore et al., 2000), but not everyone agrees on the meaning of the evidence. A brief hiatus is recognized between the PPNA and PPNB (10 500–10 100 BP) when resident populations were small or non-existent (for reasons not understood). By the beginning of the second period (PPNB), small farming villages had coalesced

(for further details see Goring-Morris and Belfer-Cohen, 2011; Zeder, 2011).

Africa

Insights from Africa provide an important counterpoint to the common narratives of the evolution of food production. Crops such as wheat, barley, lentil, and pea were introduced to the northern coast of the continent between 7600 and 7000 BP, likely from Spain (Morales et al., 2013), but indigenous resource management and domestication developed elsewhere in Africa too. One hallmark of African agriculture is pastoralism, which became an important aspect of human adaptations in northeastern Africa by 6000 BP (Marshall and Weissbrod, 2011). During the last glacial maximum, *c*.18 000 BP, much of northern Africa was too arid to support people, but by the Early Holocene it was more humid than today. Hunter-gatherers were widespread in what is now the Sahara desert where people lived near permanent water sources. Animal domestication appears to have developed in the context of these climate changes. Animal management and their subsequent domestication may have been a response to risk inherent in the Middle Holocene development of the desert regions of northeastern Africa. Early pastoralism may not have developed strictly for food production because the economy at the time was based on early codependence of people and animals, particularly the donkey and cattle. Whether these animals were domesticated is not clear because morphological changes are difficult to see. Reduced size is not necessarily an indication of animal domestication in this instance (Marshall and Weissbrod, 2011). Human diets do not appear to have been dependent on these animals but the close relationship between people and animals involved logistical arrangements of movement to pastures. These animals held important positions in the symbolic life of these northeastern African peoples, as evidenced by the prominence of cattle in rock art. Close relationships between people and domesticated animals, and possibly animal management, appear to have begun in the early Holocene between 10 000 and 8000 years ago. Domesticated cattle may have been present *c*.9000–8000 BP at Nabta Playa, a site that is well outside the natural range of cattle (Jórdeczka et al., 2013). By 5000 or 4000 BP, cattle remains are common at archaeological sites although the evidence for reliance on domesticated plants is minimal.

Sorghum, pearl millet, cowpea, African rice, and t'ef were domesticated in Africa but not particularly early. Pearl millet was being grown by Kintampo culture people (3600–3200 BP) and further evidence of landscape management comes from the extensive use of oil palm at this time, reflecting what is likely early arboriculture (D'Andrea and Casey, 2002; Logan and D'Andrea, 2012). T'ef, an extremely small-grained grass, has an archeological record that is difficult to interpret because seeds of the domesticated form are not particularly different from those of wild t'ef; however, it was likely under cultivation in Ethiopia at least 2000 years ago (D'Andrea, 2008). Sorghum was a significant component of the plant assemblage at Nabta Playa 8000–7300 BP so it may have been cultivated at the time (Wasylikowa et al., 2001), but its domestication may not have occurred until about 2000 years ago. Domesticated sorghum and African rice are present at the site of Jenne-Jeno in Mali about 2000 years ago (McIntosh, 1995). In South Africa, agriculture and pastoralism are thought to have arrived in the early Iron Age about 2000 years ago with the spread of food producers into this part of the world (for further details see Breunig and Neumann, 2002; Harlan, 1992; Morales et al., 2013).

South Asia

The origins of food production in the Indian subcontinent may involve as many as five independent areas or as few as three (Fuller, 2011). Understanding the circumstances of these origins is clouded by ambiguous plant remains, the lack of early hunting and gathering sites, as well as a scarcity of sites that provide data about the people who first developed food production. Available evidence points to relatively small groups of mobile hunters and gatherers making the first steps to food production. An exception is found in northwestern Pakistan where the earliest documented food production in South Asia is found at the site of Merhgarh, the earliest levels of which date to about 9000 BP. The crops here, as well as goats, were introduced from Southwest Asia. To what extent food production in Pakistan influenced the origins of food production elsewhere in South Asia is not known. The widespread development of food production in the Indian subcontinent in disparate regions and the fact that the wild progenitors of the earliest millets and legumes are found here strongly suggests that food production began independently, at least in some areas. Significant crops include native millets (small-grained grasses) and a dozen legumes (in particular, mungbean and horsegram). Wheat, barley, chickpea, lentil, and pea were all introduced from Southwest Asia. The latter three crops, all legumes, appear to be limited to the Indus valley in Pakistan. Domesticated rice appears many millennia later in India than in China. The circumstances under which rice became an important resource in the Indian subcontinent remain a significant outstanding issue in the study of food production in the region. The wild progenitor of rice grows in India but a sequence of remains documenting the evolution of domesticated rice here has not been found in the region. Rice, in association with other crops, is present by about 3500 BP (for further details see Fuller and Madella, 2001; Fuller, 2011).

East Asia

The origins of food production in East Asia are complex and did not follow a single pattern (for further details see Cohen, 2011; Crawford, 2011; Liu and Chen, 2012; Zhao, 2011). The last 15 years have seen significant developments in understanding the origins and development of food production in China, South Korea, Japan, and the Russian Far East. Among these regions, only China and Japan have evidence of independent origins of food production. The situation in Japan is still debated (Crawford, 2011), but in China at least three independent origins have been documented: North China, Central-East China, and tropical South China. Rice was an important technological resource, its

chaff being used to temper clay used for pottery between 10 000 and 8000 years ago in the highlands to the south of Hangzhou Bay in South China (Jiang and Liu, 2006). The extent to which it was used as food at this time is not known. Significant levels of rice management are evident by 8000 BP at the Kuahuqiao site in Zhejiang Province. From 8000 to 7000 BP, rice spread northward and was a significant resource at the Jiahu and Yuezhuang sites. Many plants important to the modern Chinese economy such as the peach, foxnut, lotus root, and water chestnut are evidenced in the archaeological remains between 8000 and 5000 BP in the lower Yangzi valley. People were also raising pigs, dogs, and possibly cattle throughout much of North and Central-Eastern China.

Initially, the most important crops in North China were foxtail millet and broomcorn millet. Broomcorn millet was widely used 8000–7500 years ago from the West through central Yellow River Valley to Inner Mongolia. Starch grains recovered from grinding stones dating between 10 000 and 8000 years ago suggest that at the very least the wild ancestor of broomcorn millet was being harvested in North China. The soybean was also being exploited at this time. Research on tropical South China is just beginning but preliminary evidence indicates that tubers and root crops such as yams were being harvested at Zengpiyan (12 000 BP) while rice production was introduced, likely from the Yangzi valley, *c*.6000 BP according to studies at sites such as Xiaojing in Guangxi province (Zhao, 2011).

Millet production spread to the Korean Peninsula sometime during the Middle Holocene. How this happened is poorly understood. By 3500–3000 BP, wet rice and dryland food production were well established in South Korea and from there moved into southwestern Japan by 2800 BP. Before food production from the mainland was introduced to Japan, local people belonging to the Jomon cultures had developed a variety of resource management strategies. Although the Jomon did not develop intensive grain-based food production, they managed nut orchards, groves of lacquer trees, and domesticated Japanese millet and a type of soybean. A close relationship with the wild boar developed too, but these animals were not domesticated.

Southeast Asia and the Islands of the Southwest Pacific

An array of tuber, root, and tree crops were domesticated in Southeast Asia, New Guinea, and the islands of the southwestern Pacific (Denham, 2011). Evidence of these is difficult to retrieve archaeologically because of the fragile nature of starchy tissue in particular and the difficulty in assessing where along the continuum from wild through domesticated forms that tree seed or nuts recovered from sites belong. Much of the discussion about plant domesticates from the region revolves around ethnographic, ethnobotanical, and linguistic data as well as delineation of prehistoric agricultural terraces, ditches, and other landscape features. For now, it appears that crops spread from New Guinea to the rest of Southeast Asia. Banana, taro, a yam, and a nut produced by an evergreen tree (karuka; *Pandanus julianettii*) are the only archaeologically represented crops. Our understanding comes primarily from the Wahgi valley, New Guinea. Mounded cultivation is evident by 7000–6500 BP followed by ditch fields *c*.4000 BP at the Kuk site and presumably banana, yam, and taro at least were under production before the landscape was engineered. Investigators believe that vegetative reproduction methods such as grafting and transplanting were favored over seed planting. Other crops that may have been domesticated in the lowlands include sugarcane, sago, breadfruit, and *Canarium*.

A strong case has been made for landscape modification in the Wahgi Valley, New Guinea, especially the creation of ditched field systems. Such systems presumably were constructed in the interests of growing taro and native yam species, long preceding the *c*.3500 BP expansion of people from Southeast Asia onto the Pacific islands. Those colonizing populations were accompanied by domestic animals (probably dogs, chickens, and pigs) and an array of domesticated tuber and root species (*see* Pacific Islands, Archaeology of; for further details see Denham, 2011).

The Americas: Mexico

Archaeologists are not in agreement on when people first arrived in the New World but it appears to have been before 15 000 BP. By 10 000–9000 BP, the first steps to food production were beginning in Mexico. These steps involved the domestication of a few plants between 10 000 and 6000 BP by relatively small groups of mobile hunters and gatherers during the Archaic period (*c*.10 000–4000 BP). Villages that relied to some extent on food production did not develop across the Mexican landscape until perhaps 4000–3500 years ago. What we know comes from only a few rock shelter and cave sites, mainly Guila Naquitz (Flannery, 1986) and Coxcatlan and San Marcos (Byers, 1967; MacNeish, 1992) in the dry interior of Oaxaca and Puebla, respectively, and the Xihuatoxtla site in the lowlands of the Balsas valley of Guerrero. At least a dozen plants of worldwide economic importance owe their domestication to the ancient inhabitants of Mexico. Among them is maize or corn (*Zea mays*), a grass native to Mexico. Yet, despite its well-known genetics, its archaeological record is not nearly as well documented as many of the old world grasses. Its wild ancestor (teosinte) is indigenous to the Balsas River drainage in western Mexico and the only archaeological record for maize in the Balsas valley consists of starch grains and phytoliths recovered from a grinding stone in contexts that appear to be older than 9000–8600 BP at the Xihuatoxtla site. Squash phytoliths are also evidenced in this context. Excavations by Kent Flannery in 1966 at Guila Naquitz (Flannery, 1986), a rockshelter in Oaxaca, have resulted in information about several other cultigens: squashes, bottle gourd, beans, and chili peppers. *Amaranthus* (amaranth), *Chenopodium* (goosefoot), *Agave* (agave, maguey). Several root crops and tree fruits thought to have been encouraged and harvested if not actually domesticated have been recovered too. Large squash seeds provide evidence that the plant was being domesticated by *c*.9000 BP at Guila Naquitz. The oldest preserved maize cobs so far discovered in Mexico date to about 6000 BP at Guila Naquitz where there is no evidence that the wild ancestor of maize grew. It was likely imported, probably from the Balsas valley. No fieldwork on early Mexican agriculture comparable to

MacNeish's and Flannery's has taken place since the 1960s (for further details see Piperno, 2011; Smith, 2005).

The Americas: Central and South America

Food production in Central and South America appears to have involved a complex mosaic of plants and animals over a broad geographic range and elevations, as well as many different regions. Given this variation it should come as no surprise that agriculture began in many different places in these regions (Piperno, 2011). Many herbaceous plants, trees, root crops, grains, medicinal plants, and legumes were domesticated in the region, and some of the more economically important ones were potato, tomato, sweet potato, manioc, peanut, chile pepper, quinoa, coca, pineapple, avocado, several squashes and beans, and cotton. Unlike the Old World, only a few animals were domesticated here. These include the llama, alpaca, and guinea pig that were domesticated in Andean South America.

The exploitation of plants that would eventually be domesticated is widespread early on. According to Dolores Piperno (2011), several species of *Cucurbita* (squash) have been recovered from Panama, Colombia, Ecuador, and Peru, from 11 750 to 8000 BP; bottle gourd was exploited as much as 11 000 BP; peanut and manioc make their first appearance in the record *c*.8500 BP in the Zaña valley of northern Peru. Bottle gourd is intriguing because the botanical understanding is that it is an African plant that spread to many parts of the world at a relatively early date (Kistler et al., 2014). Evidence for the first dispersals of manioc and peanut northward dates to about 8500–7600 BP, while based on phytolith evidence maize appears to have diffused into South America from Mexico by 8000 BP. In the western Andean foothills of northern Peru, small-scale irrigation evidences ecological engineering as early as 6500–5400 BP and by 4000 BP agriculture was well established (Dillehay et al., 2005). Similar to Mexico, the first people to heavily exploit these and other domesticated plants lived in small, seasonally dispersed settlements.

The only herd animals domesticated in the New World are the llama and alpaca. Their distribution is limited to the Andes. Intensified use, changes in patterns of mortality, and morphological changes in bones indicate that they were being domesticated between 4500 and 4000 BP (Mengoni Goñalons, 2008). Guinea pig may have been domesticated around the same time. Quinoa may also have been domesticated in the highlands by 5000 to 4000 years ago too, but the best evidence for the crop is from the Early Formative period Chiripa site *c*.3500 BP in the south-central Andes (Bruno and Whitehead, 2003).

The arid west coast of South America in Peru and Chile has its own food-producing story to tell, related to that of the highlands in some ways, but with significant differences. Preservation of even very delicate plant parts as well as textiles and human remains makes archaeological remains in the region attractive to professionals and to looters. Evidence for plant use begins early at some sites, as far back as 8800 BP for gourds, and includes many of the same species referred to above for other areas of South America. Whether these plants were wild and their natural distribution included all of these areas or domesticated in one or more regions still needs investigation. The coastal valleys of Peru currently provide the oldest directly dated evidence for beans (one lima bean pod) at *c*.5600 BP; Mexican common and tepary beans are no older than 2500 BP (for further details see Piperno, 2011).

The Americas: Eastern North America, with Comparative Reference to the Southwestern United States

Indigenous food production was being established by 4500–4000 BP during the Late Archaic period in Eastern North America. The people who began plant cultivation were focusing their subsistence activities on rich river valleys and floodplains while exploiting a range of resources from a variety of other habitats (Smith and Yarnell, 2009). The occupants of Archaic shell mound sites along the Green River in Kentucky, for instance, were managing nut trees and likely encouraging anthropogenic animal communities by burning away competing plants. Archaic peoples' understanding of ecological management techniques set the stage for subsequent food production developments. Sunflower (*Helianthus annuus*), sumpweed (*Iva annua* var. *macrocarpa*), goosefoot (*Chenopodium berlandieri*), little barley (*Hordeum pusilum*), and squash (*Cucurbita pepo*) were independently domesticated here, and by 3800 BP they formed a crop complex that became the focus of food production for cultures throughout the U.S. Midwest. Eventually maygrass (*Phalaris caroliniana*) and erect knotweed (*Polygonum erectum*) joined the crop complex. Bottle gourd was also in the region quite early but it is not native, apparently having arrived from Africa by floating on ocean currents some time before 10 000 BP (Kistler et al., 2014). When and where morphologically distinct domesticated forms appeared is not yet known.

Maize was introduced from Mexico into the U.S. Southwest shortly after 4500 BP and appears to have been used by hunter–gatherers to make their annual hunting rounds more secure rather than shifting people into becoming food producers (Wills, 1995). In fact it was not until slightly over 2000 years later (around 2000 BP) that communities of food producers appeared. In all cases, considerable use was made of game animals and indigenous southwestern plants, some domesticated, others semidomesticated or encouraged, and others harvested from wild stands (Wills, 1995). In some areas, even before crops were introduced, people managed local resources to the extent that the people may well have been involved with an agricultural ecology before crops became important resources. Maize then appeared in Eastern North America, likely introduced from the Southwest, some time between 3000 and 2000 years ago. It was a minor component of local economies until *c*.1000 BP. After that it was a critically important resource to societies in much of Eastern North America including southern Ontario and Quebec, Canada (for further details see Crawford et al., 2006; Minnis, 2004; Smith, 2011; Wills, 1995).

Discussion and Conclusions

This article interweaves domestication and agriculture in a way that implies that they are the most significant elements related to food production. This is certainly the way it is

treated by archaeology, the discipline that is primarily concerned with the topic. However, food production encompasses an array of strategies involving animal management, transplanting and encouraging desirable plants, grafting, burning to create habitats favorable to certain types of plants and animals, and the like. These strategies form an important part of modern human behavior that lies within the realm of ecological engineering or niche construction (Laland et al., 2001). Ecological management or engineering behaviors likely developed along with, and contributed to, the evolution of modern humans. The difficulty for archaeologists is determining how to recognize these behaviors especially when human populations were quite low. Future research on Upper Paleolithic (Old World) and Paleoindian (New World) human ecology will be critical to our understanding of food production developments as habitats and environments transformed at the end of the Pleistocene.

Cultures diversified around the world at the same time. The research outlined for the Ohalo II site in Israel and the latest Upper Paleolithic sites in North China attest to this. The tendency for these Late Pleistocene cultures to be viewed as primarily big-game hunters is changing because of this new research. Archaeologists are also coming to terms with the active role people have played in their local environments.

Agriculture is probably best considered as a range of human behaviors that involves people intervening throughout the life spans of specific plants and animals. Domestication involves genetic changes to plants and animals (Fuller et al., 2010; Larson, 2011; Doebley et al., 2006) that not only increases the dependence of these organisms on people but also emphasizes changes in plant parts that people exploit and in how these plants reproduce. Phenotypic or physical changes in domesticated animals in addition to behavioral changes that make them tamer are also important but archaeologists are learning that initially, at least, management of certain animals is easier to recognize by looking at their population structures. The first evidence for animal management comes in the form of a high proportion of young males, a higher proportion of older females, and, conversely, very few older males and very few younger females in archaeologically recognized populations. Domestication was an unintended consequence of strategies practiced by humans long before they made any commitment to agriculture. The difficulty for archaeologists is to sort out these behaviors in the record before intensive agriculture developed.

For now the best evidence comes from Southwest Asia, Eastern North America, and North and East-Central China but not South China. Even in these regions, significant gaps in our knowledge need to be filled. The record for South and Southeast Asia, Africa, as well as from South and Central America is significantly stronger than it was two decades ago, but archaeologists are still struggling to outline the details of late Pleistocene and early Holocene developments there.

Be that as it may, certain patterns are emerging. The evidence suggests that there were 10 or more areas where indigenous and distinctive food-producing economies developed: Southwest Asia (more than one area), Saharan and sub-Saharan Africa (perhaps with West African and East African foci), North, East-Central, and South China, Japan, Indian subcontinent (as many as six areas), Eastern North America, Mexico, Central and South America (with neotropical and highland foci), and New Guinea. Discussion of early crops in these locations centers heavily upon those that dominate modern world economies (e.g., wheat, rice, maize, soybean), sometimes to the detriment of understanding the nature and function of ancient subsistence systems, whether food producing or not. Given the present concerns about the grave dangers of monocropping on a regional, let alone a global, scale, the focus on primary crops is doubly unfortunate. Lost crops and lost varieties of current crops and domestic animals are vital resources for modern agropastoralism, but can be retrieved only through the interdisciplinary work of archaeologists, paleoethnobotanists, and zooarchaeologists, on the one hand, and molecular biologists and plant and animal breeders on the other.

Two more issues central to any consideration of how ancient food-producing economies began are chronology and explanation. Is the timing of the events in the disparate regions informative? Were the causes and processes of independent, indigenous transitions to food production essentially the same? How one answers these questions depends almost entirely on how detailed and how secure regional chronologies and databases may be. On the evidence of present chronologies, developed with a significant dependence on AMS radiocarbon dating, it appears that only in Southwest Asia and East Asia were significant developments underway by the Late Pleistocene. Significant short-term fluctuations in temperature and rainfall occurred in the late Pleistocene. No one is clear whether these changes encouraged food production. The tropics were not impacted significantly by these climate change episodes. Highly localized environmental changes related to global-scale changes may still have been crucial. Significant developments were occurring shortly after 12 000 years ago in some areas but much later in other areas such as Eastern North America and Japan.

Prime movers used to aid explanation of transitions to food production range from the older favorites, climatic or environmental change (see earlier), and population pressure to newer models drawn from economics and behavioral ecology, to competition among lineage or clan heads, or to the necessity of intercommunity trade for forging alliances guaranteeing mutual assistance in hard times (e.g., Hayden, 1996). Some of these models are quite ingenious, and plausible for specific origins cases, but they do not fit others at all, making them less than satisfactory as general explanations for the origin of food production in the human past. That abstraction is very useful for certain purposes, but self-destructs when placed in contact with all the evidential bases now available, meager though many of them are. The shift to greater dependence on food production was happening between 13 000 and 8000 years ago in most areas although it was much later in other regions such as Eastern North America, Africa, and South Asia.

Through the years scholars often cited the natural tendency for human populations to grow. A crisis point would be reached and people would be compelled to produce food rather than extract food from the wild. A number of observations negate this proposal. Human demographics are complex and dependent on culture and environment. Archaeologists are also becoming increasingly aware of the active human role

impacting the productivity of resources throughout human existence. Furthermore, the process of domesticating plants and animals is known in hindsight, but hunters and gatherers in the Late Pleistocene would not have known about domestication. The development of food-producing economies relying on these domesticated organisms appears to have been an unintended consequence of decisions people were making at specific times and places to solve immediate problems. These problems likely had little to do with paucity of resources because in most areas where we have a detailed archaeological record food production was developing in relatively resource-rich areas.

High-level, theoretical formulations must be devised and tested against independent data. Hypotheses developed from what we already know need to be examined in the context of their implications. This means collecting new data, possibly using new biomolecular and archaeological recovery techniques, and including regions that have not been investigated in any detail such as southernmost China. This way we can expand our knowledge about what, in the abstract, is indeed the most important transition in human prehistory (for further details see Bocquet-Appel, 2011; Price and Bar-Yosef, 2011).

Abstract

Food security refers to enough food at all times for a healthy and active life. In other words, countries, households, or individuals who are food secure are no longer at risk for hunger on a chronic, seasonal, or sporadically recurring basis. While some promote food security by making sure all households have adequate access to food, others mainly focus on increased food production as the best strategy. The 'Green Revolution' was such a production-based approach and is a term used to describe the changes that took place in farming in Asia and Latin America after the introduction of semidwarf wheat and rice varieties in the mid-1960s and 1970s. The term and approach have more recently been revived and reborn as the New Green Revolution in much of Africa since approximately 2005.

Food Security

Food security is commonly defined as "access by all people at all times to enough food for an active, healthy life" (World Bank, 1986: 2). While this definition makes no explicit reference to the spatial or social unit of analysis, others have focused on a particular scale. For example, Frankenberger and Goldstein (1990: 21) define the term to be a condition in which "[t]he viability of the household as a productive and reproductive unit is (not) threatened by food shortage." In these terms, food insecurity may be thought of as inadequate access to sufficient amounts of food during all or part of the year for a healthy and active life either through insufficient subsistence production or limited ability to acquire food through other means, for example, purchase, barter, or informal reciprocity arrangements. Increasingly, since the seminal work of Sen (1981), the various elements of food security are encapsulated in the idea of household food entitlements (defined as legitimate claims on food resources). Sen's insight reveals that national food audits, using the food balance sheet approach, do not necessarily correlate with household food security. The typical audit is couched in terms of an aggregate supply–demand problem in which national supply (production + stocks + imports) is compared to national demand (total population × caloric need per capita). Although not a useless exercise, national audits (where sufficient supply is often defined as national demand + 10%) (Geier, 1995) might satisfy national goals without accounting for the differing abilities of households to access food, even when it is available on the market. To phrase the problem more baldly, strategies designed to achieve national food goals do not necessarily and concomitantly achieve household and community food security. By contrast, it is reasonable to suppose that when household food entitlements are obtained, national food security goals would, of necessity, also be achieved.

Until the early 1980s, international experts had labored under the misperception that sufficient food supply – a function of homegrown production and net imports – was equivalent to food security. As such, it was argued, the best way to fight hunger was to boost agricultural production, as exemplified by the Green Revolution. United Nations experts monitored food supply in relation to the caloric needs of a country – known as the food balance sheet approach – and then assumed that all was well if the two sides were at least equal. History is riddled with examples of the poor dying of hunger when food was plentiful. Classic among these is the famine that wracked the West African Sahel during the early 1970s. While people were dying of hunger in Senegal, Mali, and Niger, peanuts – a key sauce ingredient and source of protein across the region – were being exported to Europe.

Sen's definition of food security, with its attention to access, dominated international food policy circles for about 15 years, from the late 1980s through the early 2000s. Then, after a 20-year hiatus, the global community's attention has subsequently shifted back to agriculture. The international consensus on 'food security as access' shifted to a technocratic focus on food production as the best way to solve global, and especially African food insecurity.

Early History of the Green Revolution

The term 'Green Revolution' is most commonly used in the social sciences to describe the changes that took place in farming in Asia and Latin America after the introduction of semidwarf wheat and rice varieties in the mid-1960s. If planted on irrigated land with the use of chemical fertilizers and pesticides, these crop varieties gave higher yields than traditional ones. These innovations led to a substantial increase in the yield of wheat and rice, which was sustained until the 1990s when the rate of increase of yield and output declined. The term was also applied to land reform in Eastern Europe in the 1930s and more recently to the attempts to persuade governments and business to adopt policies and practices that are not inimical to the environment.

The period immediately following World War II in South Asia and Latin America was characterized by rapid population growth, food shortages, and poverty (which were connected in the minds of the Green Revolution architects). A great variety of wheat and rice were in use, each adapted to their local microenvironment; yields were low with limited fertilizer and pesticide use. In 1966 a semidwarf variety of rice known as IR8, bred at the International Rice Research Institute in the

Philippines, was distributed among farmers in parts of India, while a semidwarf wheat originally bred in Mexico was also introduced. Where these high-yielding varieties (HYVs) were adopted, yields and output increased dramatically. This led W.S Gaud to state in a lecture in the United States in 1968: "this and other developments in the field of agriculture contain the makings of a new revolution. It is not a violent Red Revolution like that of the Soviets … I call it the Green Revolution" (quoted in Dalrymple, 1979). It is also clear that the Green Revolution was taking place in the ideological context of the post WWII Cold War. As such, part of the motivation for the Green Revolution was ideological – that is driven by Western fears that inadequate food supplies would lead to socialist political revolutions across the Global South (Patel, 2013).

The breeding of higher-yielding or disease-resistant varieties had been going on in Europe, North America, and parts of Asia since the rediscovery of Mendel's work at the beginning of the twentieth century, while the use of chemical fertilizers and applications of pesticides had been practiced since the 1920s in Western Europe, although adopted at far greater rate after 1945. More relevant were the developments in Japan. Much Japanese rice had long been irrigated, but the area irrigated was increased in the 1890s when the most successful existing rice varieties were selected and their seed distributed to farmers. Chemical fertilizers were also applied. By the 1930s, rice yields in Japan and its colonies, Korea and Formosa, were substantially above those elsewhere in Asia. Even in South Asia there had been advances in technology before 1966. Indian grain output increased by 62% before 1950 and 1964, and in Pakistan by 59% (Farmer, 1981). Although rice yields in China in the 1950s were low compared with the rest of East Asia, semidwarf rices were bred there independently of the research in the Philippines and distributed to Chinese farmers before IR8 was released.

The Nature of HYVs in the Green Revolution

The principal characteristic of the HYVs were their high response to chemical fertilizers. They were also short with a stiff straw, and so, unlike the tall traditional varieties, did not lodge with higher yields. They were insensitive to photoperiodicity and matured in about 110 days rather than 180 days; it was thus possible to grow two or even three crops in a year. The yield potential of these varieties was greater in the temperate regions of Asia and in the dry season in the monsoon region than in the humid tropics, because of the longer hours of sunshine and hence the greater potential photosynthesis available to the plant. The highest yields are achieved in areas of well-managed irrigation and with adequate amounts of chemical fertilizers. At first the new varieties were highly susceptible to disease, and pesticides were necessary to obtain the high yield potential, but later varieties have been bred with a greater resistance to pests. Breeding of new varieties of rice and wheat has continued since the 1960s, increasingly in research stations in the countries where they are to be grown. HYVs of maize have also proved successful and to a lesser extent new varieties of sorghum. Since the 1970s Chinese farmers have used hybrid rice seed. The new varieties introduced since the first HYVs are now often referred to as MVs (modern varieties).

The Diffusion of the Modern Varieties in the Green Revolution

The inputs of the Green Revolution are divisible: seed, fertilizer, and pesticides can be bought in small amounts and so in theory could be obtained by farmers with only very small holdings. In practice, however, the first adopters were generally occupiers of larger farms with better credit facilities and a greater awareness of the new technology. By the 1980s, however, there was near universal adoption in irrigated areas with no differentiation of inputs by farm size or tenure (although this may be an artifact of an unknown number of small farmers going under and leaving agriculture altogether). The principal incentive to adopt was the greater profit per hectare, in spite of the increased unit costs. At first the use of fertilizers and seeds were subsidized, and the improvement and extension of irrigation was undertaken by government. In the 1980s, however, subsidies began to be withdrawn, and the further extension of irrigation had become very expensive. The introduction of modern varieties began at different times in different countries and different regions. Rice was introduced into India, for example, in 1965 but not in South Korea until 1972. The rate of adoption also differed; by 1976 four-fifths of all the rice in China was sown with modern varieties, but only 7% in Burma, 11% in Thailand, and 14% in Bangladesh. National differences persisted in the 1990s.

Within countries there have also been major regional differences in the rate of adoption; thus in India in 1990, 95% of the rice in Punjab and Tamil Nadu was sown with modern varieties, but only one-third in Bihar and Kerala (Singh, 1997). By the 1990s some of the major international differences in the rate of adoption had been reduced, but a greater proportion of Asia and Latin America's wheat was sown with modern varieties than Africa or the Near East, while more of China's was in new varieties than the rest of Asia. But of course there is a difference in the proportion of each continent sown in wheat, rice, maize, and other crops. Little wheat or irrigated rice is grown in tropical Africa, so the proportion of these crops in modern varieties is of little significance. This distribution explains why, in the mid-1980s, modern varieties were planted on less than one-third of the total cereal area in the developing countries: only 1% in Africa, 22% in Latin America, and 36% in Asia (Tangley, 1987).

The Consequences of the Green Revolution

In the 1950s and 1960s it was feared that future population growth would outrun cereal output in Asia and increase malnutrition and hunger. This has not occurred. The rate of increase in output of both rice and wheat in Asia exceeded population growth rates between 1966 and 1995. Population increased 76% but rice output doubled; and the real price of rice fell steadily since the 1950s, halving between 1970 and 1990. Cereal consumption per capita has increased by 25%, imports have been greatly reduced, and grain reserves built up. The increase has varied between countries, and has been greater in wheat than rice output, but there have been dramatic increases in cereal harvests throughout the region. In the 1950s and 1960s increases in cereal output were largely due to an extension of the

cultivated area; since the 1960s, overwhelmingly due to the increases in crop yields following the adoption of the new HYVs.

The shorter growing season for HYVs has also allowed more double cropping in some parts of Asia. Yields have stagnated in the 1990s, however, particularly in Japan and Korea, which have the highest rice yields. The yield potential of the original HYVs has not been increased since the 1960s; the many new varieties bred since then have had greater disease resistance or better quality grain, but not greater yield potential. Additionally, in the high-producing irrigated rice areas, waterlogging, salinization, and disease have led to a decline in yields in some places. The fall in rice prices and the continued increase in import prices have squeezed cereal producers, and many have left farming or turned to more rewarding crops. In the last few years there have been renewed fears for the future of cereal output in Asia.

Criticisms of the Green Revolution

Initially the Green Revolution was greeted with extravagant praise and high expectations. These were excessive, for it was unlikely that many farmers could reach the yields obtained on experimental farms, or that all farmers could profitably use the new techniques. A barrage of criticism followed to the present, although with changing targets. Controversy remains over the social and economic effects of the Green Revolution. There are three technical reasons why interpretations may differ. First, national and state statistics in India and other parts of Asia are not reliable and so different interpretations of changes are possible, particularly with reference to land tenure, farm size, and labor. Second, it would be surprising if there were identical responses to new technology over such a vast area and population with greatly varying physical and socioeconomic environments. Third, research produces different results at different stages of the adoption cycle of agricultural innovations. It is unlikely that the consequences of technological change in the 1960s would be the same in the 1990s.

But there are other criticisms that are a result of the unequal distribution of farm sizes and land ownership. Many critics argue that the adoption of HYVs benefited the larger farmers most, and often led to increased landlessness and declining real wages. While those with larger farms (and in most of Asia more than 20 acres is a large farm and many farmers have less than 5 acres) were able to rapidly adopt the new technology and make considerable profits, smaller farmers were unable to do so and often sold their holdings to larger farmers. Many tenants were evicted to allow landowners to farm larger units. The number of landless households increased and so forced down real wages. In some areas the larger farmers adopted machinery to replace labor, and real incomes of the landless fell. Consequently income inequality increased.

Other critics pointed out that the HYVs were only profitable in irrigated areas, and that only improved varieties of wheat and rice had been bred. Furthermore, in many parts of India farmers grew other crops so the benefits of the 'Green Revolution' were limited to certain regions. The early HYV rices had an inferior taste, and although subsequent varieties were of higher quality, richer consumers still prefer the taste of traditional varieties. Other critics were alarmed that the inputs for the new farms were imported, while some believed that monoculture was replacing the diversity of cropping in traditional Asian farming, particularly the replacing of protein-rich pulses with cereals. There was rising problem of pesticide resistance among insect pest populations. This meant that increasingly large doses of pesticides needed to be applied, or new pesticide formulas developed altogether.

By the 1990s new fears replaced these traditional concerns. Yields were – and still are – stagnating and even declining as a result of waterlogging and poor drainage in irrigated areas, while chemical pollution was becoming a problem. Muldavin's (1997, 2000) work in China suggests that soil degradation related to overuse of fertilizers and pesticides is a growing problem.

Global Food Insecurity and the New Green Revolution for Africa

The problem of food insecurity remains one of the most serious challenges facing humankind. In 2012, by the UN Food and Agriculture Organization's conservative estimate, 868 million people experienced extreme chronic undernourishment, and micronutrient deficiencies affected around two billion worldwide (FAO, 2012). Sub-Saharan Africa suffers the highest prevalence of macro- and micronutrient malnutrition, and lags behind other regions in reducing hunger (Nature, 2010; IMF, 2012). In response to this problem, philanthropic foundations, industrialized country governments and aid agencies, international agricultural research centers, and African governments have come together in an unprecedented and highly coordinated effort to improve food security in Africa. Through initiatives such as the Rockefeller and Gates Foundations' Alliance for a Green Revolution for Africa (AGRA), the G8's New Alliance for Food Security and Nutrition, USAID's Feed the Future Program, and the African Union's Comprehensive African Agricultural Development Program (CAADP), these actors have committed billions of dollars to the goal of raising productivity among African smallholder farmers, on the assumption that increased yields are the key to food security, poverty reduction, and economic growth (Toenniessen et al., 2008). Equally important to this donor-led development strategy, popularly known as a 'New Green Revolution for Africa' (GR4A), is tighter integration of African smallholders into formal markets, both to improve their access to yield-boosting inputs and to encourage the sale of crop surpluses for cash (Annan, 2007). A more reliable and nutritious food supply and diminished hunger rates will, according to this approach, inevitably follow.

This new concerted effort to construct a market-based model for African agriculture constitutes a substantial shift in the way that international development actors organize their responses to hunger at the global level. Inspired by the technological revolution that transformed food production in Asia and Latin America in the 1950s to 1960s, but seeking to incorporate lessons learned from that experience, the GR4A focuses on 'scaling up' African smallholder participation in commercial input and output markets through the development of national, regional, and global agricultural value chains. This model, which relies heavily on public–private partnerships, is expected to have a profound impact on the continent's national and regional agricultural systems, local agroecologies,

and rural livelihoods (Gómez and Ricketts, 2013). However, its specific consequences for food and nutrition security – at the level of the household, and especially for women and children – remain unclear. Despite the centrality of food security goals to GR4A projects and discourses, much uncertainty remains around the policy, market, and social mechanisms that will translate increased crop yields and incomes into improved access to a nutritious food supply for all. Moreover, by conceptualizing food insecurity principally in terms of crop yields and market access, this model overlooks the many political, socioeconomic, and biophysical dynamics that contribute to hunger and malnutrition – or 'hunger vulnerability' (Bassett and Winter-Nelson, 2010).

Moreover, according to Sen (discussed earlier), the problem is that improving household food security involves more than just increasing food production. A food security approach that is sensitive to issues of 'access' targets the poorest of the poor who are habitually the most food insecure. Helping poor households in rural Africa feed themselves in an affordable manner means introducing low-cost, sustainable enhancements to farming. These improvements include intercropping or the mixing of more than one crop in a field, agroforestry, the blending of trees and crops, composting, and soil conservation measures. These reforms are critical because they enhance soil fertility and control pest problems without cash outlays for expensive chemicals and fertilizers (Snapp et al., 2010).

Agroecological alternatives to the GR4A approach may be seen in a variety of contexts, such as in West Africa where traditional subsistence farmers using plant associations and organic inputs have often fared better than those farmers heavily engaged in cash cropping with the use of chemical inputs (Moseley, 2005). Similarly, such farmers also did better than market-integrated farmers and consumers during the 2007–08 global food crisis (Moseley et al., 2010; Moseley, 2011). Other laboratories for agroecological alternatives have been Cuba following an economic crisis that forced it to become more food self-sufficient (Miller, 2007). Finally, Bezner-Kerr's (2012) work in northern Malawi (a country known for embracing inorganic fertilizer subsidies as a way to improve food self-sufficiency) shows the viability and advantage of such approaches – even when situated in a country dominated by a strong maize monocropping ethos.

Sadly, advocates of the GR4A are not pushing these types of alternative interventions. Rather, they envision a more capital-intensive approach to agriculture involving supply chains, increasingly large producers, agro-processors, expanding international markets, and farming with intensive, and often expensive, inorganic fertilizers, pesticides, and seeds. This view sometimes legitimizes long-term land leases by foreign entities, so-called land grabs, which are seen as a showcase for new production strategies. While this approach will likely improve agricultural production in sub-Saharan Africa, it will do little to improve household food security for the poorest.

Abstract

Food is a subject that seems to both slip away and to expand when one tries to understand it. We cannot simply analyze the production and consumption of food, of food diets, and of table manners, and their evolution in time and space. As food has been cooked for thousands of years, we need to integrate the notion of *cuisine*, a polysemous term with multiple significations, into the study of food. We also need to include in this domain of study the representations, discourses, and collective beliefs associated with the notion of food.

Recent advances in the social sciences – notably history, sociology, and anthropology – that deal with food reinforce this observation. While this article emphasizes the advances as well as the limits of knowledge acquired in this area in recent decades, it also seeks to take into account epistemological and methodological problems encountered in social science research in the domain of food, whether it be with the definition of food itself, with interdisciplinary difficulties, or with the synthesizing of the approaches of different disciplines dealing with a complex subject that has all the characteristics of what Marcel Mauss called a 'total social fact.'

Considered as a trivial, frivolous topic unworthy of interest for established science, the study of food long remained a domain of study limited to individual scholars, to literati, and to amateur enthusiasts.

However, we must nuance this statement of a general state of indifference to and ignorance of the subject of food, since in France – and to a certain extent also in other countries – some authors have, in their own way, been the early 'historians' and the first 'sociologists' of food, and have assigned to it an important function and a particular place in the lives of their characters and of their heroes. Balzac (1838) even went further: he did not simply describe the social and cultural role of the table place in the bourgeois society of the early nineteenth century, he defined the political aspect of food, as follows: "Food as a whole is one of the most important and most neglected parts of politics. I even dare say that it is in its infancy."

When we speak of food, what exactly are we talking about: a social fact? In this case, food would only be a subject of interest for the social sciences and the humanities. A biological fact? Then it would be in the domain of nutrition and dietetics. And if food was both a biological and a social fact, how could we articulate the biological and the sociological approaches? Finally, how could we ignore the political dimension of food inherent in the vocabulary itself? The word *régime* (food habits, diet) comes from the Latin '*regere*: govern, rule.' In ancient societies the king was the foster father of his people, and organized their food diet, i.e., the way food was produced and consumed. The word *régime* thus applies both to its political and nutritional aspects.

Much more than its ambiguity, it is the complexity of food that has long been a problem for specialists who sought to define it, whatever their discipline of origin. Replying to those who thought that its study fell within the scope of biology, Dr. Jean Trémolières, a biologist himself, pointed out (1975) that:

> "Our relationship with food, the most basic of all our relationships, remains on a completely subconscious level …" and he stressed that in consequence we need to combine different and complementary disciplinary approaches to understanding man's eating behavior. A behavior that is "very curiously established …. We do not sit down to table to rebuild depleted reserves. We sit down to table and we choose our food driven by psycho-sensory and symbolic motivations that are only linked to biochemical motivations by all that we think and feel."

For long the social sciences did not see nutrition as an object worthy of their attention. Thus at the end of the nineteenth century, as Louis Bourdeau pointed out (1894), historians still largely ignored the subject:

> […] Disdainful of the conditions of common life they (historians) dislike the unhealthy curiosity attached to this low aspect of life and remain in an ideal world, foreign to the needs of prosaic necessity. People eat little in their writings. Their heroes – like the novelists' – seem to be ethereal heroes, freed from vulgar necessities, who live off glory and passion…

And what is true for historians is true as well for sociologists. Indeed, one only has to refer to the writings of Emile Durkheim (1894) and the founding principles of this new discipline that he wanted to establish ("consider social facts as things" and "the causes of a social fact should be found in another social fact") to understand the reluctance and hesitation of the emerging discipline of sociology when dealing with nutrition.

Indeed, Durkheim considered initially that nutrition, drinking, and eating are too organic in nature to be considered as social facts: "each individual drinks, sleeps, eats and reasons, and it is in society's interest that these functions be carried out regularly. So if these facts were social, sociology would not have an object of its own and its scope would be confused with that of biology and psychology."

However, he then underlined that what characterizes social facts is that "they are ways of acting, thinking and feeling external to the individual, and which are endowed with a coercive power that they impose on him."

He proceeded to give drinking and eating as examples of social facts:

> We can also confirm by a typical experiment this definition of a social fact: it suffices to observe how children are raised … It is obvious that all education consists of a continuous effort to impose on the child ways of seeing, feeling, and acting that he would not have adopted on his own. From the start, he is forced to eat and drink at regular times … he is forced to be clean, quiet, and obedient; and later he is forced to take others into account and to be respectful of customs and established practice.

It is not surprising that sociologists considered nutrition as a minor topic or at least not as worthy as religion or art.

As Claude Grignon observed (1995):

> This lack of academic prestige undoubtedly comes partly from the fact that the social dignity of subjects tends to reflect on the value of objects, including, it seems, in the minds of some sociologists. With this point of view, sociology is lagging behind art: everyone now knows that a painting of an apple can be a masterpiece.

Another obstacle that hampered research for many years related to the plurality and the diversity of the scientific disciplines that studied nutrition. Each discipline having a specific object and methodology (ethnology considers primitive peoples, sociology studies modern developed societies) addressed only one aspect of such a complex problem, but nevertheless was not particularly disposed to cooperating with other disciplines. In spite of declarations of principle in favor of the synthesizing of disciplines or in favor of interdisciplinarity!

In fact, nutrition has only recently become a legitimate object of research for the social sciences and the humanities.

In France, the first investigations into the economic and social history of nutrition were carried out after World War I by the School of Annals. Lucien Febvre, Marc Bloch, and then Fernand Braudel (1967) and their disciples studied both the production and the consumption of food and also diverse food régimes and their variations in space and time. Marc Bloch and Lucien Febvre (1954) were thus the originators of research into the 'types of cuisine,' which delineate in France the frontiers between regions, which use butter, oil, and fat for cooking.

The publication in 1970 of a 'Cahier des Annales' (Casebook of the School of Annals) marked the beginning of the development of a history of nutrition. Food was perceived as a new domain of historical research to be explored. In addition to an original article by Marc Bloch on food used in ancient France, the volume included several articles on medieval food régimes, thereby highlighting the importance of economic and quantitative history in this domain.

The first French food historians primarily addressed issues of quantity, of supply, of famines and shortages, or of the price of food: the essential notion was then what 'food ration' could be determined for each social class in the time and space in question.

In France in the final decades of the twentieth century, the cultural history of food began to take precedence over its economic and social history, while opening up to other social sciences such as sociology, anthropology, psychology, and economics. Jean Paul Aron (1967, 1973) was one of the pioneers of this new approach even before the rediscovery of the work of Norbert Elias, a German sociologist and historian. In his book *Uber den Prozess der Zivilisation* (On the Process of Civilisation, 1939), which has lastingly influenced food historians, Elias had analyzed the processes by which a society gets 'civilized': i.e., by which it adopts practices and techniques to control corporal impulses. He was particularly interested in practices of politeness and courtesy, but also studied the formation of table manners in Western civilization. After the publication of the translation of his book into French in 1973 and 1975, historians – Jean-Louis Flandrin and his disciples, Léo Moulin (1988) – analyzed the history of tastes and dietary practices. The same orientation in other European countries (Mennell, 1985; Flandrin and Montanari, 1996) has resulted in a significant overall development of historical research (Becker, 2012) and in the publication of a first general synthesis (Flandrin and Montanari, 1996).

If food is a subject of research that is both hard to pin down and which expands as soon as one tries to identify it precisely, it is because it is a *total social fact*, to use the concept defined by Marcel Mauss (2007), which thus designated every social fact "which involves in some cases the entire society and its institutions and in other cases only a very large number of institutions […]. All these phenomena are both legal, economic, religious and even aesthetical and morphological," and which thereby constituted a major research challenge, namely the construction of a social science of nutrition.

Nutrition

In the word *alimentation* (nutrition), there is *aliment*, which does not have the same meaning in French as in English, and whose definition is problematic.

Aliment in French is what feeds and nurtures both body and spirit. It is a very old word, which first appeared in 1120, coming from the Latin noun *alimentum* and the Latin verb *alere*: to nourish.

In the plural form, *aliments* (which first appeared in 1690) designate the means of existence necessary for a human being to survive.

As for *alimentation* (nutrition), which first appeared in 1412: it designates the action of nutrition, whereas *aliment* designates a nutritional object.

Initially, as the *Littré* dictionary reminds us, the French used the term *viande*, which comes from the Latin *vivenda*, to designate the things necessary to sustain life.

It is worthy of note that one of the first cookbooks, written by Taillevent in 1375, was called *Viandier* (Laurioux, 1997).

In English, even though the word 'aliment' exists, it has long been replaced by 'food.' And Americans say 'food is fuel.' So there are two different concepts involved: food as an object, the product of science and technology, and food as a symbol of what helps man to survive. There are also two different cultural attitudes involved: on the one hand, that of catholic countries and, on the other hand, that of protestant countries.

Over and above the study of the production and consumption of foodstuffs, of their usages in many diverse and various food régimes, the history and the sociology of food are faced with many changes – in time and space – in the social and

symbolic significance of food: changes of names and changes in the foodstuffs themselves. Ancient authors did not write about the same food that we do. What were the tastes of those foodstuffs? With the industrialization and the globalization of modern food production, innovations have multiplied and new meat-based diets have replaced grain-based ones, which had remained stable for centuries.

In old times or new, food has been consumed by respecting rules and rituals, if only because of the sacredness of food in traditional civilizations (Varagnac, 1941). The activities that relate to the acquisition, preparation, or consumption of food have been considered as sacraments. Thus, in the era of Christian civilization, bread and wine were at the heart of the celebration of the worship of the cult and mystery of the Lord's Supper.

Paul Valéry (1933) wrote:

> Bread and wine are at the core of Christianity.
>
> Catholicism requires them. Bread, wine and the concept of substance.
>
> The basic operation that defines Catholicism is the change in substance of two products developed by the industry of man. Or bread and wine are wheat and vines and processes of baking and winemaking….

The same applies to the Last Supper, the last meal of Christ and the archetype of the meal represented hundreds of times in Western painting.

Food and how it is consumed – meals – are thus powerful cultural identity markers. Suffice it to recall the place of rice in Asian civilizations or of corn in pre-Colombian America.

Do we choose our food? When the individual chooses his food, he takes into account certain constraints of income, of socioeconomic status, of availability, and of preferences depending on his belief system (i.e., what is allowed by his culture) and on his reference group.

The question then merges with that of food régimes, of their evolution over time, of their diversity in space, and of their variations according to the socioeconomic conditions and cultures being considered. Since the research done by Le Play (1878) and Maurice Halwachs (1913), we know that the share of food in family budgets not only varies according to income but is also a marker of social status.

With regard to the production and consumption of food, very numerous sociological analyses of inequalities and their impact on health and well-being (such as the obesity pandemic in the world) have been undertaken. But however accurate they are, these empirical studies and statistics do not enable us to fully understand the relationships and interactions that individuals have with their food, because they do not sufficiently integrate analyses of dietary behavior.

This question is more important today than ever because the distinction between food production and food consumption has been put into question both by consumer movements like Slow Food, which view consumers as coproducers, and by studies on institutions such as the restaurant, which show that chefs are both producers and mediators of taste, and even themselves *gastronomes* ('gourmets').

Cooking

Food is also *cuisine* (the art of cooking). However, words that refer to cooking are not the same in different languages. In English, one distinguishes between *the kitchen* and *(the art of) cooking*; in German between *die Küche* and *die Kochkunst;* in French *la cuisine* means both the kitchen space and the preparation of food. The concept itself is polysemous, with several meanings.

Before sociologists began to analyze this domain, ethnologists and anthropologists tried to define the meaning of this activity that came into existence with the invention of fire and the cooking of foodstuffs.

Claude Lévi-Strauss (1965) saw in the passage from raw to cooked food and in the appearance of cooking the birth of "a language in which each society encodes messages that allow it to signify a part of what it is" or as "the manifestation of its structure unless, without knowing it, it is resigned to reveal its contradictions." He used a linguistic approach to draw up an inventory of the distinctive characteristics of different types of cooking that he called *gustèmes*, and to define binary oppositions. Moreover, he emphasized the prominence of fire, which transforms raw food into cooked food, establishing a separation between nature and culture. Considering cooking as a universal activity, he built a 'culinary triangle' underpinned by a double opposition between culture and nature and between processed and unprocessed food. Raw food, unprocessed, is opposed to cooked food, which is culturally processed, and to rotten food, which is naturally processed. Cooking methods are part of this triangle: something roasted relates to the raw category (it is put in direct contact with fire without intermediaries, and its cooking is rarely complete); something boiled relates to the rotten category (it deconstructs food in a similar way to decay, by the double mediation of water and container); and smoked food relates to the cooked category (it is a 'deep and slow' way of cooking, without any other intermediary than air). Prepared dishes, depending on their method of cooking, have different degrees of prestige in a constant relation from one society to another. Thus, the roast would in most kitchens be considered as a ceremonial dish to be served to guests, while boiled food, cooked in a pot, would be an intimate family dish for a closed circle of people. Because of the high level of abstraction of the 'culinary triangle' approach, analysis of actual practices sometimes reveals counterexamples, but we need nevertheless to acknowledge the opposition between different types of prepared foods that consistently appears within every society.

For the British anthropologist Mary Douglas, food is a code. She therefore seeks to 'decode,' to decipher the specificity and variability of cultural facts and worldviews of cultures, groups, or social classes. Assuming a universal need for taxonomic consistency, she presented in her famous book *Purity and Danger* (1971) an interpretation of the prohibitions of the Book of Leviticus in terms of classification anomalies. She showed that each natural milieu relates to a specific animal category: thus "in the firmament one finds winged two-legged poultry, in the water scaled fish swimming with fins, on earth four-legged animals that jump or walk." The sullied animals are the hybrids, those who do not fit into a category. Conversely, "only the animals that fully fit in their class are pure." She showed that in the Jewish culture, sanctity is associated with unity, integrity, and perfection, so

much so that "dietary prescriptions simply develop the metaphor in the same direction." Thus, for Mary Douglas, in general: "food taboos are rooted in the way we structure our overall experience of life."

On the other hand, cultural anthropology – particularly after the work of Margaret Mead (1943) – defines eating habits as "ways in which individuals or groups of individuals, in response to social and cultural pressures, choose, consume and exploit certain portions of available food supplies."

Closer to us, Claude Fischler (1990) formulated 'the principle of incorporation,' which declares that the absorption of food involves incorporating its properties on both a real and on an imaginary level. We become what we eat.

In the domain of cooking, history and sociology have progressively identified three distinct areas of study:

- The space called the kitchen. The kitchen as we know it today has not always existed: in the West it became a separate entity only in modern times. This space, separated from other rooms of the house or apartment, is also socially determined by the functions performed by its occupants, traditionally servants and women. It follows that the sociology of cooking is at the crossroads between history and the sociology of women and of the sexual division of labor.
- The techniques for preparing, cooking, and preserving food as well as their evolution over time: this covers the history and sociology of technology and of innovations.
- The men and women who work in kitchens: chefs, cooks, housewives, and amateurs. How can their activity be defined? Is cooking a science or an art? In reality, the history and sociology of culinary creations, or simply of culinary production, inevitably involves analysis of the status of cooks and its evolution throughout time (Drouard, 2004).

Representations, Discourse, and Symbols

Finally, food is the matter of representations and beliefs. It is symbolic. We do not only eat nutrients, i.e., proteins, lipids, or carbohydrates, but symbols as Jean Trémolières already declared (1975):

> Food, above and beyond its biochemical composition, becomes a source of pleasure and well-being by revealing the kind of sensations that we love and choose. Thus it becomes 'symbol'.

Hence, the central question of the choice of foodstuffs and our relationship with them. In every society, rankings and choices are made: there are 'pure' food choices and 'unclean' food choices, food that is allowed and food that is forbidden, food that we like and food that we dislike.

As Claude Lévi-Strauss said, food should not only be good to eat, but also good to think about (Lévi-Strauss, 1962). This passion for classification that produces the differentiation between what is clean and what is dirty, between what is pure and what is impure, between what is beautiful and what is ugly, and between what is masculine and what is feminine, is at work all over the world because it is at the root of food practices, of food prohibitions, and ultimately of food diets.

Hence also the discourse on the art of good eating. Gastronomy is one of the most important examples.

Based on *nomos* (law in Greek) and *gaster* (belly), *la gastronomie* (gastronomy) is the law or rule of the belly.

The word appeared for the first time in the four line poem by Joseph Berchoux "*La gastronomie ou l'Homme des champs à table*" ("Gastronomy or the Man of the Fields at Table") published in 1800.

It replaced the words *gourmand*, *glouton*, *goulu*, and *gourmet*, all synonyms for greedy or glutton, that had previously been used to qualify the art of eating or the sin of gluttony.

The term *gastronome* (gourmet in English) began to be used in 1803 and *gastronomie* (gastronomy) first appeared in the Dictionary of the French Academy in 1835.

Historians and sociologists have developed approaches to gastronomy that, while considerably overlapping, remain distinct.

What is gastronomy? A 'French passion' among others, to borrow the title of a book by Jean-Robert Pitte (1991). Is it *La Grande cuisine* or *La Haute Cuisine* as Priscilla Parkhurst Ferguson (1998) repeatedly (but incorrectly) claimed when she defined gastronomy on numerous occasions as "the pursuit of culinary excellence"?

In fact, even if they are often confused with each other and used interchangeably, the two terms *grande/haute cuisine* (fine cooking) and gastronomy do not have the same meaning.

The notion of a gourmet as someone in need of *bonne chère* (good food) can only be properly appreciated, as Pascal Ory wrote in 1998, in that he lives in an environment of gastronomic discourse and literature (completely distinct from culinary literature such as recipe books written by chefs and cooks) written for and supporting him.

Without minimizing the importance of the gastronomic discourse and of gastronomic literature, Alain Drouard (2010) sees in gastronomy a myth: a narrative based on collective beliefs and representations of the excellence of French cuisine and its centuries-long preeminence over other national cuisines.

Born after the French Revolution, this myth has accompanied the establishment of what he calls the system of contemporary French cuisine: a set of relations of dependence and interdependence between the three main groups involved: food critics, chefs, and lovers of fine cuisine.

It is a fact that there is no gastronomy without food critics; i.e., without both a discourse on the art of good food and a gastronomic literature composed of guidebooks and gourmet magazines.

There is also no gastronomy without 'gourmet' restaurants which serve *Grande Cuisine* or *Haute Cuisine* (Fine Dining) to a wealthy clientele: a luxurious and sumptuous cuisine, which was codified in the early nineteenth century by Antonin Carême and reviewed by Auguste Escoffier at the beginning of the twentieth century.

And there is no gastronomy without culinary artists. After the famous artists of the nineteenth century (Carême, Viard, Beauvilliers, Urbain Dubois, Jules Gouffé, and Escoffier), Michelin-starred chefs now carry forward the torch of French gastronomy.

Initially expounded by gourmets and cooks, the myth of French gastronomy grew and flourished in the nineteenth century before spreading over time into the general population and being disseminated abroad by French chefs.

Sociologists for their part focus on the production and the dissemination of both the culinary and the gastronomic discourses.

Thus the sociologist Priscilla Parkhurst Ferguson considers texts devoted to gastronomy as having themselves a function in the culinary system.

In line with the analyses of Pierre Bourdieu (1979), she studies the formation of an autonomous gastronomic domain in France in the nineteenth century as the product of culinary texts.

In her book *Accounting for Taste; The Triumph of French Cuisine* (2004), she argues that "the centrality of French cuisine in the Western world for the past 300 years is intrinsically linked to the extension and depth as well as the prestige and authority of the culinary discourse that it supports and thanks to which it is amplified, magnified, glorified and disseminated."

Conclusion

The history of food has developed with widespread input from other social sciences: anthropology, ethnology, and sociology, which stress the fundamental role of food and drink in the social process.

Today it is a field in full expansion in all of Europe and in North America: it seems to have acquired a real legitimacy in historical studies, being considered less systematically than before as a 'minor' topic. The creation in 2002 of the European Institute of the History and Culture of Food, located in Tours in France, has enabled the bringing together of many researchers from various disciplines – historians, sociologists, and anthropologists – for regular seminars and various publications, especially the journal *Food & History*, launched in 2003.

In Italy, the Slow Food movement has founded a University of Gastronomic Sciences, a private institution whose diplomas are now recognized by the Italian state.

The table place has now become a vantage point for the many-faceted scrutiny of human societies, as aptly described by Jean-Pierre Poulain in his book *Sociologies de l'alimentation* (Sociologies of Food) (2002).

If this field now sometimes seems to take on the aspect of a vast construction site, the current proliferation of research studies would, however, tend to rule out the prospect of a synthesis of knowledge or of a general sociology or history of food being achieved any time soon. The multiplicity of disciplinary approaches and techniques being used are in the framework of an increasing internationalization, even globalization, of research activities. In English-speaking countries, this whole field is now aptly referred to as simply 'Food Studies.'

Forecasting

Kenneth C Land, Department of Sociology, Duke University, Durham, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Forecasting comprises of the formation of expectations about future states or processes of social entities, such as populations or subpopulations thereof, and associated entities, such as economies and political and social institutions. This article commences by describing and giving examples of empirical applications of four methods of forecasting that have been developed, and are widely used, in the social sciences: leading indicators, quantitative trend analysis, formal forecasting models, and qualitative (theoretical–institutional–scenario) analysis and forecasts. This is followed by a section on limitations of forecasting. All social science forecasts are subject to deterioration of their accuracy with increasing temporal distance from the initiation point of the forecasts. This is due to the complexity of social systems to which forecasting models and the data from which they are estimated are only an approximation, the evolving nature of such systems, and the fact that the forecasts sometimes are just elements in the social system to which some actors respond, thus changing their behavior. It is concluded that forecasts should incorporate prediction intervals that grow with increases in the forecast horizon and the forecasts should be updated frequently.

Introduction

Forecasting refers to the formation of expectations about future states or processes of specific historical entities. Forecasting involves the estimation or calculation of expected future events or developments from a conceptual model. At the most informal level, the conceptual model can be a heuristic model based on individuals' life experiences and the particular social, cultural, and economic circumstances in which they live, as in the formation of expectations about the routine activities and rituals to take place on a given day. At the other end of the spectrum, the conceptual model can be analytic, formal, and complex based on numerical measurements, equations, simulations, and projections.

The most widely known forecasts by social scientists are economic and demographic forecasts, whereas natural scientists are associated with weather, climate, earthquake, and ecological forecasts (Land and Schneider, 1987). But these disciplines produce forecasts of many other social and natural phenomena and there are interstitial topics, such as energy, transportation, and technological forecasting, to which both have contributed.

The subject of forecasting, encompassing both methods of forecast construction and substantive applications thereof, is very large and would require a large volume for adequate description. Accordingly, this article will be highly focused. The next section describes four widely used methods of forecast construction. This is followed by a section on limitations of forecasting.

For purposes of this article, forecasting will refer to the formation of expectations on outcomes of study in the social sciences for social entities, such as populations or subpopulations thereof, and associated entities, such as economies and political and social institutions. This excludes applications of forecasting tools in clinical settings wherein the focus is on expected trajectories of health or behavioral outcomes for individuals.

Within this specified context, forecasts can be made for single-outcome variables or multidimensional distributions of outcomes at a specific time or time horizon into the future from the date of the forecast. The methods of construction of forecasts range from combining simple extrapolations of past performance with human judgment to elaborate methodological formalisms based on universal laws or accounting identities, or some combination of lawful behavior, extrapolation, and judgment. The 'future' forecasted can be near or distant. The scope of forecasts can encompass the world's physical/social/economic systems or a single local phenomenon. The uses of forecasts range from their fulfillment of a statutory requirement for practical policy uses to an assessment of their explanatory value in a scientific sense.

Methods of Forecasting

To focus the exposition, four methods of forecasting that have been developed, and are widely used, in the social sciences and business will now be described: leading indicators, quantitative trend analysis and extrapolation, formal forecasting models, and qualitative (theoretical–institutional–scenario) analysis and forecasts. Examples of empirical applications of each method will be included in the descriptions.

Leading Indicators

The *leading indicator approach to forecasting* in the social sciences has been most extensively developed and applied to economic and business forecasting, due very much to the work of the National Bureau of Economic Research (NBER) and one of its founders Wesley Mitchell (1927). It is based on the view that market-oriented economies experience business cycles of expansion and contraction within which repetitive sequences occur and that these sequences underlie the generation of the business cycle itself (Lahiri and Moore, 1991). The *leading economic indicator* (*LEI*) *approach* focuses on finding repetitive sequences, explaining them, and using them to forecast emerging stages of the current business cycle.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10544-6

The LEI approach differs from efforts to construct structural models of the economy – econometric models (described in more detail below) – which do not differentiate business cycles from other economic fluctuations, except possibly seasonal variation (Lahiri and Moore, 1991). The LEI construct has no fixed requirements on the duration of expansions or contractions, their amplitude, or their scope because the observed sequences – leads and lags – can be quite variable over time and are often systematically different at peaks and troughs, and because cycle phases vary widely in duration. The LEI emphasis on cycles has contributed to its longevity and helped it to spread around the world. Early signals of recession or recovery are of high salience to the actions of business officers, policy makers, job seekers, and investors. In the 1930s and 1940s, a group of NBER economists, including Moses Abramovitz, Arthur Burns, Milton Friedman, Gottfried Haberler, Wesley Mitchell, and Geoffrey Moore, developed a system of leading, coincident, and lagging indicators of business cycles.

For the United States, the system is maintained and published monthly by the Conference Board, a global independent business membership and research association. The components of the Conference Board's Leading Economic Indicators Index are the following statistics:

1. *Average weekly hours* (*manufacturing*) – Average weekly hours is a leading statistical indicator for changes in unemployment, as adjustments to the working hours of existing employees are usually made in advance of new hires or layoffs.
2. *Average weekly jobless claims for unemployment insurance* – The Conference Board reverses the value of this component statistic from positive to negative because a positive reading indicates a loss in jobs.
3. *Manufacturers' new orders for consumer goods/materials* – Increases (decreases) in new orders for consumer goods and materials usually mean positive (negative) changes in actual production, which makes this a useful leading indicator.
4. *Vendor performance* (*slower deliveries diffusion index*) – Vendor performance is estimated from a monthly survey conducted by the National Association of Purchasing Managers (NAPM). This statistics measures the time it takes to deliver orders to industrial companies. Vendor performance leads the business cycle because an increase in delivery time can indicate rising demand for manufacturing supplies.
5. *Manufacturers' new orders for non-defense capital goods* – As stated above, new orders lead the business cycle because increases (decreases) in orders usually mean positive (negative) changes in actual production and perhaps rising demand. This statistic is the producer's counterpart of new orders for consumer goods/materials component.
6. *Building permits for new private housing units*. An increase (decrease) in this statistic is indicative of more (less) activity in housing construction.
7. The *Standard & Poor's 500* (*S&P 500*) *stock index* – The S&P 500 is considered a leading indicator because increases (decreases) in stock prices reflect investor's expectations for the future of the economy and interest rates.
8. *Money Supply* (*M2*) – The money supply statistic measures demand deposits, traveler's checks, savings deposits, currency, money market accounts, and small-denomination time deposits. M2 is adjusted for inflation by means of the deflator published by the federal government in the periodic Gross Domestic Product (GDP) report. Bank lending, a factor contributing to account deposits, usually declines when inflation increases faster than the money supply, which can make economic expansion more difficult. Thus, an increase in demand deposits is indicative of expectations that inflation will rise, resulting in a decrease in bank lending and an increase in savings.
9. *Interest rate spread* (10-year Treasury vs Federal Funds target) – The interest rate spread (often referred to as the yield curve) indicates the expected direction of short-, medium-, and long-term interest rates. Changes in the yield curve have been the most accurate predictors of downturns in the economic cycle. This is particularly true when the curve becomes inverted, that is, when the long-term returns are expected to be less than the short rates.
10. *Index of consumer expectations* – This is the only component of the leading indicators that is based solely on expectations. This statistic leads the business cycle because consumer expectations can indicate future consumer spending or tightening. The data for this component come from sample surveys conducted by the University of Michigan Survey Research Center and is released once a month.

Figure 1 contains graphical representations of the Conference Board's Leading and Coincident Economic Indices from January 1999 through May 2014. Periods of economic recessions are shaded in gray. It can be seen that the Leading Economic Index turns down, signaling the oncoming 2008–09 Great Recession well before the Coincident Economic Index, the downturn of which marks the official beginning of the recession. The Leading Economic Index also turns up, signaling an oncoming economic expansion well before the Coincident Economic Index, an upturn of which marks the official beginning of an expansionary period. At the international comparative level, the Organisation for Economic Cooperation and Development (OECD) in Paris, France, publishes leading indices monthly for 34 OECD member countries plus Brazil, China, India, Indonesia, Russian Federation, and South Africa.

The LEI approach to economic forecasting persists because of its ability to survive repeated evaluations of its performance (Lahiri and Moore, 1991, pp. 2, 3). This does not mean that all of the indicators remain unchanged forever. Indeed, the need to change the list of indicators in the LEI occurs every few years because new indicators and time series become available, because research has produced some new results, or because the economy has changed. In brief, two important aspects of the LEI are that they are easy to understand and every component indicator needs periodic review.

Quantitative Trend Analysis and Extrapolation

Quantitative trend analysis and extrapolation is a second major approach to forecasting. Among other empirical applications,

Figure 1 The Conference Board's Leading Economic Index, June 2014. Source: The Conference Board.

quantitative trend analysis and extrapolation is a part of the methodology of the *technical analysis* of stock market trends. In technical analysis, the developmental characteristics (e.g., gaps, reversals, trend lines of highs and lows, and trend channels) of prices of corporate stock equities traded in stock exchange markets, using both visual and quantitative properties, have been developed and applied for several decades (Edwards et al., 2013). There also is a tradition of *application of logistic and other S-curve models* to time trends of data in order to extrapolate/forecast population growth, life expectancy, the spread of a new disease such as AIDS, energy prices, the diffusion of innovations and new products/devices, and so forth (see, e.g., Modis, 1992).

In the social sciences more generally, *population projections* are a prototypical empirical application of quantitative trend analysis and extrapolation. For instance, the U.S. Census Bureau periodically produces projections of the United States resident population by age, sex, race, and Hispanic origin. These projections are produced using a *cohort-component method* that decomposes changes in the age–sex–race/ethnicity counts of the population obtained from a decennial census year into three components of change from year to year: *births* into the population at age zero, age-specific *deaths* to the population, and age-specific net international *migrants* (immigrants into the population minus emigrants from the population) into the population (U.S. Bureau of the Census, 2012). Application of this method to the production of annual age–sex–race/ethnic-specific population projections from a base year thus requires assumptions about yearly changes in these three demographic components of change (future births, deaths, and net international migration).

As a specific example, the Census Bureau National Projections for the years 2012–60 were produced using a cohort-component method beginning with an estimated base population for July 1, 2011 as follows (U.S. Bureau of the Census, 2012). First, components of population change (mortality, fertility, and net international migration) were projected. Next, for each passing year, the population was advanced 1 year of age and the new age categories were updated using the projected survival rates and levels of net international migration for that year. A new birth cohort was then added to form the population under 1 year of age by applying projected age-specific fertility rates to the average female population aged 10–54 years and updating the new cohort for the effects of mortality and net international migration. The assumptions for the components of change were based on time-series analysis of historical trends as follows.

Age-specific fertility rates were calculated and projected for women aged 10–54 years from birth registration data for 1989–2009, which were compiled by the U.S. National Center for Health Statistics (NCHS). The birth registration data were used in conjunction with the Census Bureau's Intercensal Estimates to produce a series of age-specific fertility rates by mother's race and Hispanic origin for five race- and Hispanic-origin groups: (1) non-Hispanic white, (2) non-Hispanic black, (3) non-Hispanic American Indian or Alaska Native (AIAN), (4) non-Hispanic Asian or Pacific Islander (API), and (5) Hispanic (of any race). Race and Hispanic origin was assigned

to projected births based on the race of the mother, the racial composition of men in the projected population, and the 2010 Census distribution of race and ethnicity of women and men with children less than 18 years of age in the household. Sex was assigned to projected births within each race- and Hispanic-origin group. The sex ratios (males per 100 females) of future births were set to equal the average of the sex ratios of births for the period from 1989 to 2009, within each of the five race- and Hispanic-origin groups. The age-specific fertility rates then were projected to 2060 by assuming convergence by 2100 of the age-specific fertility rates of all five race- and Hispanic-origin groups to the average age-specific fertility rates of the non-Hispanic white group for the years 1989–2009 (1.83 births per woman).

Only one series of mortality rates was projected for the 2012 National Projections. Mortality rates were calculated from NCHS-compiled death registration data for 1989 to 2009. These rates were used in conjunction with the Population Estimates Program's Intercensal Estimates to produce a series of mortality rates by age and sex for three race- and Hispanic-origin groupings. Mortality was projected based on projections of the life expectancy at birth (e_0) by sex. Changes in life expectancy at birth by sex were modeled assuming that the complement of the life expectancy (difference between an upper bound value, A, and life expectancy values) would decline exponentially:

$$C(t) = A - e_0(t) \qquad [1]$$

where $C(t)$ = the observed complement of life expectancy at birth at time t, A = the upper asymptote of life expectancy, and $e_0(t)$ = the life expectancy at birth at time t. The complement of life expectancy was then projected for future dates as:

$$\widehat{C}(t) = \widehat{C}(t_0)^{er(t-t_0)} \qquad [2]$$

where $\widehat{C}(t)$ = the observed complement of life expectancy at birth at time t, r = the rate of change in the complement of life expectancy at birth, and $\widehat{C}(t_0)$ = the model complement of life expectancy at time t_0. The parameters r, $\widehat{C}(t_0)$, and A were estimated simultaneously by minimizing the sum of squared errors (SSE) between the model and the observed values of life expectancy, by sex, for the years 1999 through 2009. It was assumed that the complement of life expectancy for each of the three race- and Hispanic-origin groups would change at the same rate as for the total country for each sex.

Projected values for the complement of life expectancy for each group for selected years from 2010 through 2060 were produced by assuming that the rate of change in the complement of e_0 is the same for each subpopulation as it is for the total country. Mortality rates by age were then produced using the most recent observed rates by sex- and race-origin group, the trajectory of life expectancy values, and an ultimate life table. To get an ultimate age pattern of mortality by sex, the United Nations' single age versions of the extended Coale and Demeny model life tables were used (United Nations, 2010). The West model mortality rates with life expectancy values of 87 for males and 91 for females were selected. Using the Coale–Demeny West model, age-specific central death rates were projected for each of the three race-origin groups by sex using a Census Bureau algorithm, which creates life tables for years that have intermediate life expectancy estimates by finding the interpolation factors for the most recent and next death rate inputs that would result in the desired life expectancy at birth value (Arriaga and Associates, 2003). The interpolation is done on the logarithms of the death rate values.

The 2012 National Projections include a Middle/Main series and three alternative series. These four series of projections provide results for differing assumptions for net international migration. The alternative series were based on assumptions of Low, High, and Constant levels of net international migration. The Constant series was produced by holding the level of net international migration from the Middle series for 2012 constant from 2012 to 2060. The High and Low series were produced by varying the level of net international migration of the foreign-born from the projection used in the Middle series, ±30%, respectively. All other methodology and assumptions used in the Low, High, and Constant series are the same as those used in the Middle series. The three alternative series are useful for analyzing potential outcomes of different levels of net international migration relative to the Middle series.

Table 1 presents the resulting projections of the resident population for 2012 through 2060 for the Middle series and the three alternative series based on Constant, High, and Low projections of international migration. In the Middle series, the population is projected to increase from 314 million in 2012 to 420 million in 2060. The Constant Migration series lowers the 2060 projected count to 393 million, the High Migration series raises this to 442 million, and the Low Migration series yields 398 million.

The 2012 Census Bureau National Population projections have been described and presented in some detail in order to illustrate an important application of quantitative trend forecasting in the social sciences. In addition to the National Population projections, the Census Bureau produces subnational projections for each of the US states. The cohort-component method recently has been generalized and extended to the projection of both national and regional populations by household structures/composition (Zeng et al., 2013, 2014). Key features of these demographic and other applications of quantitative trend analysis and projections are the application of relatively simple statistical models (e.g., minimum least-squares estimates of time trends) and the presence of an accounting identity that coordinates the various component projected series combined with considerable expert substantive knowledge of the subject matter of the forecast.

Formal Forecasting Models

Formal forecasting models, based on mathematical and statistical equations with empirically estimated parameters, are another widely used tool for forecasting. As noted by Land and Schneider (1987, pp. 9–12), forecasts in the social and natural sciences using formal models often are based on one or more universal laws or identities. An example is the classical accounting identity used on econometric models:

$$C_t + I_t \equiv Y_t \qquad [3]$$

which states that, by definition, aggregated consumption (C) for some collectivity (such as a nation) plus aggregate investment (I) is identically equal to aggregate income (Y) in

Table 1 Projections of population for the United States, 2015–60

Year	Middle series population estimates	Constant net international migration estimates	High international migration series	Low international migration series
2015	321 363	321 219	321 595	321 130

Source: U.S. Census Bureau, Population Division, Release Date: December 2012.

any time period (t). The National Income and Product Accounts contain this and other identities.

Another example: Systems of national and regional demographic accounts – counts of stocks and flows of people among demographic and/or social statuses such as age and occupational categories (Long and McMillen, 1987) – lead to the population transformation identity:

$$I_{t-1,t} \equiv P_{t-1,t} O_{t-1,t} + B_t \qquad [4]$$

This identity says that a column vector of population inflows into a fixed geographical unit (such as a nation) from time period $t-1$ to period t ($I_{t-1,t}$) is identically equal to the product of an outflow transition proportions matrix from $t-1$ to t ($P_{t-1,t}$) times a column vector of population outflows (survivors) from $t-1$ to t ($O_{t-1,t}$) plus a column vector of births and net migrants in period t(B_t). In scalar form for total population aggregates, eqn [4] is the population accounting identity that lies beneath the population trends/projection analyses reviewed in the previous section. When members of the population are classified by demographic and/or social statuses (e.g., age, location of residence, employment status, occupational category, marital/union status, etc.), the full vector–matrix representation of eqn [4] is necessary.

From a physical science point of view, identities such as those in eqns [3] and [4] are specific instances of the law of conservation of mass. More generally, conservation laws are the natural science analog of social science accounting identities (Land and Schneider, 1987, p. 10). Both in natural science and in social science forecasting, formal models proceed by specifying parametric models/equations for one or more elements of the accounting identities. An econometric example is the classical Keynesian parameterization of the C_t in eqn. [3] as a linear function of current national income (Y_t):

$$C_t = a + cY_t \qquad [5]$$

where a and c are constants that can be estimated by simultaneous equation econometric methods. This parameterization, termed a behavioral equation, expresses the Keynesian specification that, in the short run such as a year, aggregate consumption is the sum of autonomous consumption (a) plus the current national income scaled by the marginal propensity to consume (cY_t). When combined with the specification that aggregate net investment (I_t) is fixed or autonomous in the short run, eqns [3] and [5] can be solved to determine C_t and Y_t (see, e.g., Brems, 1968).

The foregoing exposition illustrates *two key properties of the structural models approach to forecasting* (termed econometric models when applied to model the economy) to the development of formal forecasting models, be they of social or natural phenomena. First, the models often include one or more accounting identities/conservation laws. Second, the models incorporate parametric representations of one or more of the component elements of the accounting identities.

Illustrative of this, Pescatori and Zaman (2011) describe three broad categories of models that have been developed and used by the U.S. Federal Reserve Board to forecast the US and world economies over the past 50 years, each with its own strengths and weaknesses: structural, nonstructural, and large-scale models. S*tructural macroeconomic models* are built using the fundamental principles of economic theory, often at the expense of the model's ability to predict key macroeconomic variables like GDP, prices, or employment. *Nonstructural models* are *primarily statistical time-series models* (taking the form of Auto-Regressive Integrated Moving Average (ARIMA) for single time series or Vector Auto-Regressive (VAR) models for multiple time series or variations thereon; see, e.g., Granger and Newbold 1986; Woodward et al. 2012) – that is, they represent correlations of historical data that incorporate very little economic

structure, and this fact gives them enough flexibility to capture the force of history in the forecasts they generate. Indeed, it has been shown that the accuracy in various substantive contexts that the accuracy of single-period-ahead forecasts from ARIMA models is extremely difficult to beat (Nelson, 1973). In macroeconomic forecasting, these statistical time-series models are used to produce unconditional forecasts that generate the expected future paths of economic variables and provide the most accurate forecasts if the overall monetary policy regime does not change. The third category, *large-scale models*, is a kind of middle ground between the structural and nonstructural models. They are like nonstructural models in that they are built from many equations, which describe relationships derived from empirical data, and they are like structural models in that they also use economic theory, namely to limit the complexity of the equations. Their large size has the advantage that relationships can be selected from a huge variety of data series, making it possible to provide a thorough description of the economic condition of interest. For example, structural models rarely feature highly specific variables such as 'car sales,' while large-scale models often do.

This characterization of macroeconomic forecasting models, especially the distinction between structural models and nonstructural/statistical time series models, applies generally across forecasting in the social sciences. Briefly, structural models seek to represent behavioral and other structural relationships between exogenous variables determined outside the system being modeled and as well as the internal relationships among the endogenous or outcome variables of the system. By contrast, statistical time series models seek to model one or more time series of observations on the outcome variables in terms of their systematic properties purely as temporal phenomena. Articles on formal models of forecasting, both structural and time series, with applications to business, economic, demographic, and social phenomena are published in the *International Journal of Forecasting* and *Foresight: The International Journal of Applied Forecasting* by the International Institute of Forecasters (http://forecasters.org/), which was founded in 1981 for the objective of developing and furthering the generation, distribution, and use of knowledge on forecasting.

Qualitative Trend Analysis and Forecasts

A fourth general class of approaches to forecasting can be termed *qualitative trend analysis methods*. These methods pertain to the forecasting of general features of society and take the form of theoretical–institutional–scenario analyses. Daniel Bell's (1973) treatise, *The Coming of Post-Industrial Society*, on the transition in the late-twentieth century from an industrial societal form to a postindustrial form is a leading example. Bell posited that the United States in the late-1960s and 1970s was transitioning from an industrial form of society to a postindustrial form characterized by three key elements: (1) a shift from economy based on manufacturing to one based on services, especially the creation, processing, and distribution of information; (2) the increasing importance of theoretical knowledge and centrality of new science-based industries; and (3) the rise of new technical elites and the advent of a new principle of stratification that emphasize the dominance of the professional and technical classes – and that other developed societies would follow a similar transition. Bell's analysis was based, in part, on quantitative data on employment trends in the mid-twentieth century United States, but it largely was a social forecast about a change in the *social framework* of society "… the structures of the major social institutions that order the lives of individuals in a society" (Bell, 1973, p. 8), especially the distribution of persons by occupation, the education of the young, and the regulation of political conflict.

A decade later, John Naisbitt (1982) published *Megatrends*, in which he identified 10 major trends shaping the evolution of American society in the last quarter of the twentieth century. These included transitions from a national economy to a world economy, from hierarchical forms of organization to networking, and from either/or personal choices (e.g., either we get married in a male/female union or we do not) to multiple options (many forms of domestic unions from traditional heterosexual marriage to cohabitation to serial marriages/unions to same sex marriage).

The qualitative, institutional–structural transitions forecasted by Bell and Naisbitt have been highly evident in societal evolution over the decades since 1970. These forecasts are part of the innovation and development of a field of scholarly inquiry termed futurology or futurism. Just as the International Institute of Forecasters was established to further the development of formal forecasting models and methods, the World Future Society (http://www.wfs.org/) and its journal, *The Futurist*, was established in 1966 to foster the development of ideas about the future, including forecasts (especially qualitative forecasts), recommendations, scenarios, and alternatives.

The body of qualitative trend analyses and forecasts produced by futurists over the past four or five decades is huge, of which the examples cited here are only illustrative. The methods of analysis used in futurist studies also are quite diverse. Bell (1973), for example, based his projections of the postindustrial society very much on a theoretical–conceptual analysis of changes in the nature of economic production and the implications this would have for occupational structures and for the educational system and its relation to occupational success and stratification systems. This is illustrative of one class of approaches to futurist studies, namely, a *theoretical–conceptual–institutional analysis of implications of technological, demographic, or political changes*. Related to this is the use of *possible scenarios of futures* that might develop as a consequence of scientific technological advances, demographic, or political changes; an example is Mayes (2014) in which possible scenarios for recent developments in synthetic genomics/biology (= biology + engineering/editing of genomic structures) are sketched. A third approach is that on which Naisbitt's (1982) research was based, namely the *content analysis* of the verbal content of more than 2 million articles published in some 6000 local US newspapers during a 12-year period. Content analysis is a method of identifying specified characteristics of messages that has its roots in US intelligence efforts in World War II, led by the sociologist Paul Lazarsfeld and the political scientist Harold Lasswell, to obtain information on enemy nations from their published newspapers. Since the 1970s, qualitative trend followers such as Naisbitt have made extensive use of this method. With the

development and widespread use of the Internet, similar content-based trend-identification tools have also been developed by providers of major search engines. An example is *Google Trends* (http://www.google.com/trends/), which tracks how often a particular search term is entered relative to the total search volume across various regions of the world and in various languages.

Limitations of Forecasting

All demographic, economic, and social forecasts have limitations with respect to accuracy. Demographic forecasts of national and other large populations, as noted above, deal with movements of demographic processes of fertility, mortality, net migration, and multistate status changes from time period to time period. These processes change relatively slowly. Even so, demographers consider population projections for up to a decade or so beyond the initiating time period to have informative forecasting information, whereas projections beyond this time horizon are considered to be scenarios that may or may not develop (Zeng et al., 2014).

While the time horizon for macroeconomic forecasts typically is shorter (monthly or quarterly) than that for annual population projections, their limitations are even stronger. As Pescatori and Zaman (2011) noted, it is unlikely that macroeconomic models will ever provide perfectly accurate forecasts, because forecasts are ultimately just another variable in a system in which there are many rational actors (e.g., managers of production and distribution corporate units, bank managers, investors) for whom an economic forecast may change their behavior. In fact, the economic actors who attend most closely to forecasts are the people whose behavior is most likely to affect the future course of the variables forecasted. Both the structural and nonstructural varieties of economic forecasting models have been extensively developed and improved since the 1970s. However, most models, including the Federal Reserve Board's models (Greenspan, 2013, p. 7), failed to predict the financial crisis of September 2008 that led to the Great Recession of 2008–2009. This failure may be partly attributed to the models' failure to fully incorporate the growing role of the financial sector or the worldwide financial and trade linkages that globalization has generated. A key point is that economic systems evolve and change over time and it is difficult to incorporate these changes into the macroeconomic models until a forecasting crisis has raised their salience. Even so, the lack of forecasting ability does not prevent models from being useful devices that can help policy makers in making decisions.

Similar considerations apply to the accuracy of forecasts based on qualitative trend analyses. That is, while the accuracy of qualitative forecasts is more difficult to assess because of their more ephemeral nature (the author knows of no existing large-scale systematic assessment), it likely is the case that some such forecasts hit the mark, some do not, and some work temporarily but lose their accuracy as the system being forecasted evolves. For instance, of the 10 major trends shaping the evolution of American society in the last quarter of the twentieth century identified by Naisbitt (1982), a fair assessment is that 5 have evolved and lasted in the long-run (Industrial Society > Information Society, National Economy > World Economy, Hierarchies > Networking, More Development in the north United States > More Development in the south United States, and Either/Or > Multiple Options), while 5 may have had some staying power in the 1980s but have not been as widespread or lasted as strongly or long (Forced Technology > High Tech/High Touch, Short-Term > Long-Term, Centralization > Decentralization, Institutional Help > Self-Help, Representative Democracy > Participatory Democracy).

To understand these limits to forecasting accuracy, it is helpful to recall Land and Schneider's (1987, pp. 17–19) analysis of the accuracy of weather and social science forecasting. Briefly, weather forecasts are based on nonlinear partial differential equations of hydrodynamic flow that depend continuously on both boundary and initial conditions. To produce accurate forecasts of indefinitely long range from such equations would require perfect boundary specifications and an observational net of weather stations finer than the radius of the smallest atmospheric eddy; otherwise, small weather events 'hidden beneath the net' eventually become amplified, with time into the forecast horizon from the initiation point, into larger uncertainties by inherent instabilities in the nonlinear system. In brief, the finite resolution of observations on weather variables (such as temperature, barometric pressure, relative humidity, wind speed) is due to the fact that atmospheric measurements are available at only a finite number of grid points at which there are weather stations. Forecasts then are based on initial conditions that assume that the weather variables for points between stations are equal to the average or interpolated values between the stations. Because the interpolated values of the initial conditions on the grid often deviate from atmospheric microevents (e.g., thunderstorms) that lie within the grid, the resulting 'errors in initial conditions' in weather forecasting models ultimately places limits on their accuracy. Observational and theoretical studies have found that the limit of weather predictability is about 2 weeks (Somerville, 1987).

In the social sciences, corresponding limits to forecasting accuracy are due to the fact that, no matter how much disaggregation and cross-classification is introduced into the forecasting models and data, at some point a statistical average value must be estimated for each subcategory or subpopulation. But such an average, even if it is not subject to measurement or sampling error, likely ignores some population heterogeneity that is 'hidden' relative to the specified resolution of the model. This, combined with the property that social science models often are based on linear approximations to underlying nonlinear, multilevel interactive mechanisms, produces forecast errors that, again, become amplified with time into the forecast horizon from the initiation point. Accordingly, it is not surprising that demographic, economic, and social forecasts, whether quantitative or qualitative, have errors that deteriorate with an increasing forecast horizon from the point of initiation.

In brief, limits to forecasting accuracy are the reason that forecasters emphasize the need to incorporate uncertainty into forecasts (Goodwin, 2014). Uncertainty can be due to several sources, including uncertainty in the structure of models, errors in measurement of variables, and errors in estimation of model parameters. To the extent possible, therefore,

forecasts should incorporate prediction intervals that grow with increases in the forecast horizon, such as the high and low bounds on the U.S. Census Bureau National Population projections described above, if possible, these intervals should be based on probabilistic analyses, and the forecasts should be updated frequently.

Abstract

Foreign direct investment (FDI) is defined as the ownership of assets in one country by the resident of another country. Studies explaining the upsurge of FDI in the post-World War II era focused on US multinationals and their worldwide operations in manufacturing industries. As a result, initial theoretical discussions emphasized the behavior of firms belonging to oligopolistic industries. The growth of FDI from Japan and the newly industrializing nations, as well as FDI in service industries, called for an eclectic approach toward explaining the dynamics of FDI. Other studies on FDI emphasize the location patterns of FDI within a host country and the nature of the impact of FDI on financial markets, technology, employment, competitiveness, and trade.

Foreign direct investment (FDI) is defined as investment into business units in another country with an equity stake sufficient to influence the strategy of the foreign business. It is distinguished from foreign portfolio investment (FPI), which is conducted solely with financial aims as investors take small equity stake in firms abroad without direct involvement in the business. Following OECD guidelines, most national statistics and scholarly studies use 10% equity as a threshold whether a foreign investment is classified as FDI or FPI (OECD, 1996). Firms undertaking FDI and hence operating business in multiple countries are known as multinational enterprises (MNEs).

Firms can undertake FDI in many forms (Peng and Meyer, 2011: chapters 6 and 12). The most common distinctions are between acquisitions and greenfield, that is whether a local firm has been taken over or a local operation has been built from scratch 'on a greenfield' (or nowadays more likely by renting few offices). The other key distinction is by the level of ownership. Foreign investors can take full ownership to establish wholly owned subsidiaries, or they can share ownership with other investors. Among shared equity arrangements, the most common are firstly the creation of a joint venture with a local partner, that is a new entity is created in which a foreign and a local partner hold equity, and secondly partial acquisitions, where a foreign investor acquires a stake in an existing local firm.

Trends of FDI

The volume of FDI is hard to measure because of definitional and measurement issues. The most commonly cited data are based on balance of payments statistics, and capture the financial flows between associated firms, with some corrections for issues such as retained profits. There are a number of methodological limitations to these data; for example, they do not capture projects for which a foreign investor raises capital in capital markets of the host country; but they do include capital flight into firms based in tax havens. However, at high levels of aggregation, these data outline the broad trends in the recent history of FDI (UNCTAD, various years). The annual flows of FDI show a highly volatile pattern that is strongly associated with business cycles. This is not only because in boom periods firms have more capital to invest and more ambitious expansion plans, but the values of acquired firms are inflated by high stock market valuations.

Since the 1970s, there has been a massive shift in the countries of origin of FDI. In the 1970s, the USA accounted for about 54% of global FDI flows, followed by the UK with 12%. At the time, developing or emerging economies accounted for less than half of a percentage of global FDI firms. In the next decades, Japanese and West European multinationals gained prominence while the US–UK dominance declined. For example, Japanese firms surged in the late 1980s and accounted for over 20% of new FDI. German and French companies have in the 1990s exceeded 10% of global flows in several years in the year 1990. In the mid-2000s, a new trend emerged with multinationals from emerging economies, especially China and Russia entering the global stage. By the year 2012, their share had increased to over 20% while the US accounted for 23% and the UK for 6%.

With the diversity of countries of origin, the diversity of FDI also increased in other dimensions. Early investment was often in the form of market-seeking investment by manufacturing businesses between industrialized economies. By the early 1990s, FDI was also frequently used to establish global value chains exploiting variations in human capital and production costs. By the 2000s, emerging economies had also become a major destination not only for market-seeking FDI but for businesses aiming to reduce their production costs. Following liberalization of service sectors in many countries, service sector businesses such as banks and insurances, construction firms, or e-commerce businesses joined manufacturing and primary sector firms as major investors. With the diversity of origins, their ownership pattern also changed: while the typical investor of the 1970s was listed on a stock exchange in New York or London, investors in the 2000s included many firms that are controlled by family business groups or are owned by entities of the state.

Motivations of FDI

The motives inducing firms to engage in FDI are commonly categorized into four types: market seeking, efficiency seeking,

resource seeking, and natural resource seeking (Dunning and Lundan, 2009). The vast majority of foreign investors are market seeking and aim to sell their products or services beyond their home market. Some market-seeking investors establish local production sites, acquire distribution channels, or service infrastructure (for example, in telecommunications). However, most market-seeking operations are very small as they may entail only a sales office or representation. These only account for a very small part of the financial flows reported for FDI. Firms typically start their international operations with such market-seeking investment in neighboring countries, and at later stages of their internationalization establish operations in more distant countries.

Efficiency-seeking FDI aims to enhance the operational efficiency of a business operation, for example, by lowering production costs, in particular labor costs, or by exploiting economies of scale. Efficiency-seeking FDI thus frequently uses lower cost production sites to serve international markets, for example, by locating a production base in Eastern Europe to serve Western Europe, or by using East Asia as a global production hub. Natural resource-seeking investment aims to explore natural resources such as oil, gas, coal, or minerals for sale in global markets or in the investor's home country. For example, oil majors have invested in emerging economies around the world seeking scarce resource deposits. Because of the value of such natural resources, such investments tend to involve relatively large capital investments (and hence a large entry in the balance of payments), but they are also more likely than other types of projects to trigger political objections.

Strategic asset-seeking investment is defined as the acquisition of assets such as technologies and brands overseas with the aim to not only compete in the host country, but to use the acquired assets to enhance competitive positions in global markets, and in the home market. Such strategic investments are typical for firms from countries aiming to accelerate catch-up with the global technological edge, such as Japanese in the 1970s, Koreans in the 1990s, and Chinese in the 2010s (Meyer and Thaijongrak, 2013).

Location of FDI

FDI enters virtually in all countries of the world; some developing countries and socialist countries used to prohibit most forms of FDI inflow, but such restrictions have largely been phased out since the early 1990s (with a minor trend reversal after the 2008 financial crisis). However, different types of investors seek different locations, dependent on their investment motives and their abilities to manage overseas operations. Market-seeking FDI tends to focus on large and fast growing markets. Traditionally, the most sought after markets were in industrialized economies, but the fast growth of emerging economies attracted an increasing share of investors in search of new markets. Efficiency-seeking investment traditionally had a North–South dimension to it (with West–East added in Europe since the 1990s), but even that has become more diverse. For example, Indian or Chinese companies may invest in selected activities such as sourcing of high-tech components in Europe or North America to enhance the quality of products they sell both globally and in their home markets.

Natural resource-seeking investment is focused on specific resources available only at select locations around the world. In consequence, natural resource seekers account for many of the largest FDI projects in countries with unattractive local markets or high economic or political risks. For example, many Chinese investments in Africa in the 2000s and 2010s are motivated by the quest for resources ranging from oil and gas, to minerals, and to farm produce; in fact the Chinese government provides ample support for such investments because securing access to resource is a prime objective of national economic development policy. In contrast, strategic asset-seeking investment tends to focus on technology clusters in the developed economies such as California or South-West Germany, where catch-up companies aim to embed themselves in local business communities to learn and to enhance their own capabilities.

While globalization opened opportunities to engage in FDI in distant parts of the world, the overall location pattern of FDI remains strongly influenced by economic, geographic, and cultural distance. Especially in early stages of their internationalization, firms tend to invest in countries close to their country of origin where they face fewer obstacles to doing business. Once they build experiential knowledge to operate in the global economy, they become more capable of managing larger commitments and operate in more distant countries (Meyer and Thaijongrak, 2013). Even among the largest multinationals, most have the bulk of their operations in one particular region of the world, with sales to other regions accounting for only a small part of their revenues (Rugman and Verbeke, 2004).

Impact

FDI influences its host economies in multiple ways, both positively and negatively. While these influences have been widely debated in the scholarly literature (for a review, see Meyer, 2004), they offer no simple answers as to whether host countries benefit from their presence. Many FDI projects generate positive effects, while some generate negative effects. Yet, the conditions that would attract positive or negative effects remain an issue of extensive political discussions and scholarly analysis.

FDI can benefit the local economy, for example, through creating employment in areas of high unemployment, by taking over bankrupt local firms, or by introducing new technologies that ultimately also benefit local business partners – or even unrelated firms observing technology in action. However, foreign investors may also crowd out local firms when they introduce more efficient and labor-saving production processes that lead local firms to surrender. Problematic in terms of benefits to the host economy can be projects where foreign investors attain a quasi-monopoly position in the host economy and can extract rents, or when they are protected from competition by poorly designed or enforced regulations.

Foreign investors also introduce new standardization practices on issues such as environment, labor, or transparency. Since multinationals tend to prefer standardized practices across their global operations and they are subject to more scrutiny by NGOs and by the media, their standards tend to be higher than those of local firms. However, the standards employed in

developing countries are often lower than those in the home country, which leads to critique from NGOs. Elsewhere, labor-intensive operations may not respect relevant legal standards, which triggers critique by NGOs; though these cases are typically associated with local firms or with outsourced manufacturing rather than with FDI. The ethics of international operations, as FDI or in other organizational forms, is complex and cannot be discussed here comprehensively.

Summary

Firms establish FDI projects overseas to expand the scope of their operations, to reach new markets, to enhance the efficiency of their overall operation, reduce their production costs, and to tap knowledge pools or natural resources overseas. FDI thus is a major vehicle through which MNEs contribute to the economic integration of the world economy. Foreign investors make important contributions to host economies, which may normally benefit the host economy, but in some incidences may also be harmful.

Foreign Language Teaching and Learning

Aleidine J Moeller and Theresa Catalano, Teaching, Learning and Teacher Education, University of Nebraska-Lincoln, Lincoln, NE, USA

Abstract

Foreign language teaching and learning have changed from teacher-centered to learner/learning-centered environments. Relying on language theories, research findings, and experiences, educators developed teaching strategies and learning environments that engaged learners in interactive communicative language tasks. A shift in foreign language pedagogy from a specific foreign language method to the measurement of language performance/competency has resulted in a change in the role of the teacher from one of authority/expert to that of facilitator/guide and agent of change. Current developments point to public pedagogy, social media, and action research as additional ways to foster intercultural competence and language learning.

Foreign language learning and teaching refer to the teaching or learning of a nonnative language outside of the environment where it is commonly spoken. A distinction is often made between 'foreign' and 'second' language learning. A second language implies that the learner resides in an environment where the acquired language is spoken. In the area of research, the term second language acquisition (SLA) is a general term that embraces foreign language learning and investigates the human capacity to learn languages other than the first language once it has been acquired. Scholarly inquiry into the acquisition of a nonnative language includes the disciplines of psychology, linguistics, language pedagogy, education, neurobiology, sociology, and anthropology. Inquiries of learning and teaching innovations have provided new insights into successful language learning strategies and environments designed to increase language achievement and proficiency.

Definition

A language is considered foreign if it is learned largely in the classroom and is not spoken in the society where the teaching occurs. Study of another language allows the individual to communicate effectively and creatively and to participate in real-life situations through the language of the authentic culture itself. Learning another language provides access into a perspective other than one's own, increases the ability to see connections across content areas, and promotes an interdisciplinary perspective while gaining intercultural understandings. Language is the vehicle required for effective human-to-human interactions and yields a better understanding of one's own language and culture. Studying a language provides the learner with the opportunity to gain linguistic and social knowledge and to know when, how, and why to say what to whom National Standards in Foreign Language Education Project (NSFLEP) (2014).

Language scholars distinguish between the terms acquisition and learning: 'acquisition' refers to the process of learning first and second languages naturally, without formal instruction, whereas 'learning' is reserved for the formal study of second or foreign languages in classroom settings. One usually distinguishes between the relatively effortless process of SLA by children and the more formal and difficult SLA by adults. Foreign language education refers to the teaching of a modern language that is neither an official language nor the mother tongue of a significant part of the population.

Theories of Language Learning

Foreign language learning and teaching have undergone a significant paradigm shift as a result of the research and experiences that have expanded the scientific and theoretical knowledge base on how students learn and acquire a foreign language. Traditionally, learning a foreign language was thought to be a 'mimetic' activity, a process that involved students repeating or imitating new information. Grounded in behaviorist theories of learning and structural linguistics, the quality and quantity of language and feedback were regarded as the major determinants of language learning success. A popular method of teaching in the 1950s, called the audio-lingual approach (ALM), promoted an imitation and practice approach to language development. The major figure in the ALM classroom was the instructor who was cast into the role of drill sergeant, expert, and authority figure. Students were relegated to practicing and imitating patterns to a point of automatic response in the belief that the learner would then merely have to slot in lexical items appropriate to the conversational situation. It was believed that the first language interfered with the acquisition of the second language and that a transfer would take place from the first to the second language, resulting in errors. In 1959, Noam Chomsky's review (Chomsky, 1959) of B.F. Skinner's (1957) Verbal Behavior dramatically changed the way of looking at language by arguing that language was a rule-governed activity, not a set of habits. Chomsky argued that stimulus–response psychology could not adequately account for creativity involved in generating novel utterances using internalized rules. The creative aspect of language behavior implies that the human mind is involved in deep processing of meaning rather than in memorized responses to environmental stimuli. Chomsky's view of language and cognitive psychology, dubbed generative transformational grammar, regarded language acquisition as an internal thinking–learning process. Chomsky claimed that children are biologically programmed for language and have an

innate ability to discover for themselves the underlying rules of a language system. Chomsky's ideas led to the demise of structural linguistics, behaviorist psychology, and the ALM approach to language learning.

An alternative theoretical position emerged centered on the role of the linguistic environment in combination with the child's innate capacities in acquiring language. This position (interactionist) viewed language development as the result of a complex interplay between innate language capacities of the learner and the learner's environment. Unlike the innatist position (e.g., Chomsky, 1959), the interactionists claimed that language had to be modified to the ability of the learner. According to Long (1985), language input was made comprehensible by simplifying the input, by using linguistic and extralinguistic cues, and by modifying the interactional structure of the conversation. Long maintained that speakers adjust their language as they interact or negotiate meaning with others. Through negotiation of meaning, interactions are changed and redirected, leading to enhanced comprehensibility. Long proposed that learners, in order to acquire language, cannot simply listen to input, rather they must be active co-constructive participants who interact and negotiate the type of input they receive.

Each of these theories of language acquisition addresses a different aspect of a learner's ability to acquire a language. Behaviorist explanations explain systematic aspects, whereas innatist explanations explain the acquisition of complex grammar. Interactionist explanations assist in understanding how learners relate form and meaning in language, how they interact in conversation, and how they use language appropriately.

More recently, researchers have identified nine contemporary language learning theories: Universal Grammar, Autonomous Induction, Associative-Cognitive CREED, Skill Acquisition, Input Processing, Processability, Concept-Oriented Approach, Interaction Framework, and Vygotskian Sociocultural Theory (VanPatten and Williams, 2008). Some of these theories share a linguistic view of language cognition, others view it from a psychological point of view and in the case of Sociocultural Theory, a social approach is taken. The Universal Grammar (UG) and Autonomous Induction theory share the linguistic view that learners have innate knowledge of grammatical structures that is not learned through mere exposure to input. They believe that linguistic knowledge is predetermined and is independent from experience. Learning is believed to occur incidentally by deduction from innate abstract knowledge.

The psychological view of language cognition is represented by the following theories: Associative-Cognitive CREED, Skill Acquisition theory, Input Process theory, Processability theory, Concept-Oriented Approach, and the Interaction Framework. While these approaches share a psychological view of cognition, there are some distinct differences. The Associative -Cognitive CREED, Input Processing, Processability, and Concept-Oriented theories view language acquisition as implicit and language learning is presented as an incidental and a subconscious learning process. However, according to the Skill Acquisition theory there is a conscious processing in language acquisition that requires explicit instruction in order for deliberate learning to occur.

The most prevalent and most widely held theory, the Sociocultural Theory (SCT) proposed by Vygotsky, views cognition as a social faculty. According to this theory, participation in culturally organized activities is essential for learning to occur. Active engagement in social dialogue is important. Learning is regarded as intentional, goal-directed, and meaningful and is not a passive or incidental process but is always conscious and intentional. According to Ellis and Larsen-Freeman (2006) learning from exposure comes about "as part of a communicatively rich human social environment" (p. 577). This is discussed in more detail later in this article.

Emphases in Second Language Research and Teaching

Research has revealed that knowledge of language structures demonstrated on discrete-point tests does not ensure communicative ability when the measure of language knowledge is one of more spontaneous language use. Further studies have shown that there is little correlation between the rules learners are taught and their developing knowledge of the second language. Language scholars have demonstrated that certain aspects of second language learning cannot be altered through instruction, and that intermediate, nonnative-like second language competencies, known as stages of interlanguage, characterize the progression of SLA. Selinker (1974) viewed interlanguage as an intermediate system located on a continuum stretching from the native language to the target language. Corder (1978) stated that, in the interlanguage process, the learner constantly and progressively adjusts the native language system to approximate the target language system more closely (restructuring continuum). Corder noted that not all learners showed evidence of transfer from native language to target language and suggested that there was a uniformity about the way second language learners progress and that they follow approximately the same sequence of development regardless of their native language (developmental continuum). More recent studies in the area of interlanguage such as Vidaković's study of Serbian learners of English support Corder's findings that not only is a learner's interlanguage a continuing developmental process, but that it is also systematic in its development. However, new findings contain evidence that the acquisition paths of the two linguistic systems of the learner are influenced by a rich interplay of mostly universal (as opposed to language-specific) factors and show similarities unrelated to the first or second language (2010). According to this view of SLA, the controlling factor is the innate ability for learning language that all human beings possess. Pica (1983) determined that all language learners progressed through a fixed series of stages, known as developmental sequences, in learning particular linguistic subsystems, such as word order, negation, or relative clauses. In English negation, for example, when communicative samples were examined, it was revealed that both foreign language and second language learners progressed through the same four-stage sequence, defined in terms of placement of negation. Ellis (1986) reviewed several studies that involved Japanese, Spanish, German, and Norwegian children, adolescents, and adult learners. He concluded that all English-as-a-second

language learners pass through the following prescribed set of stages: (1) 'no' phrase, for example, 'No drink'; (2) negator moves inside the phrase, for example, 'I no can swim'; (3) negator is attached to modals, for example, 'I can't play this one'; and (4) auxiliary system is developed and learner acquires correct use of not and contractions, for example, 'He doesn't know anything.' This suggests that learners make particular kinds of errors at particular stages in the acquisition of a structure. Each stage marks some kind of restructuring in the mind of the learner regarding that particular structure. Structure evolves over time.

Is L2 learning possible without rules? In the absence of rules, low-level associative learning that draws on information driven processes supported by memory is possible but does not lead to knowledge of a systematic rule. Future research should investigate whether all aspects of a second language are equally learnable by implicit means or whether more complex aspects of the second language may require more conceptually driven processing in order for associations to be formed (Ellis, 2002).

Recent trends in foreign language research have increasingly focused on multilingualism and the interplay of multiple linguistic systems in the language learner. One area of multilingualism that has been much examined is cross-linguistic influence (also known as language transfer, linguistic interference, the role of the mother tongue, native language influence, and language mixing) (Odlin, 2003). Studies point to the complexity and dynamic nature of the multilingual system and have identified a number of factors involved in cross-linguistic influence in the acquisition of a foreign language, particularly of a third language. Some of these factors include (psycho) typological distance (e.g., the similarity of the languages or perceived similarity), foreign language effect (a coping strategy used as a type of 'foreign language cognitive mode'), proficiency level, and recency of use or context of the interaction. Studies also provide evidence for stronger language transfer between L2 and L3 rather than L3 and L1 (De Angelis, 2007; Wrembel, 2010). Moreover, current studies of cross-linguistic influence tend to treat each aspect of language acquisition separately (e.g., phonological transfer and transfer of literacy skills) and reveal that not each type of transfer works in exactly the same way or is influenced by the same factors.

Learner-Centered Instruction

Two communicative approaches, the input model and the input interaction model, represent two models of foreign language theory and teaching that investigate the language acquisition process from the perspective of the learner. Krashen (1982) is the principal advocate of the input model of foreign language teaching. His theory is grounded in (1) Chomsky's generative linguistics; (2) research on the effectiveness of different second/foreign teaching methods; and (3) research on affective factors (such as motivation, anxiety, and personality). Krashen posited that SLA occurs when the learner comprehends the language input in a low-anxiety, high-motivation situation, and proposed that the teacher's role is to create such a learning environment. Krashen further claimed that conscious grammar teaching/learning is effective only in a monitoring capacity to check for grammatical accuracy, not in the acquisition of the second language itself.

Because classrooms remained a major setting for language learning, the pursuit to determine those elements that enhanced classroom language achievement became particularly important. Why do two learners who seemingly have the same instructional opportunity achieve varying levels of language proficiency? Investigations focused on individual skills or abilities and environmental factors that may impact foreign language achievement and proficiency.

Individual cognitive (e.g., intelligence, aptitude, or ability) and affective (e.g., attitude and personality variables) factors were analyzed. Skehan (1986) noted a fairly strong relationship between cognitive variables such as aptitude, intelligence, and language achievement for learners in foreign language classrooms. Other factors analyzed include the age of the learner. Researchers have typically aimed at understanding how early versus late learning affects successful acquisition, and discussed this issue in terms of a critical period of acquisition in which language acquisition seemed to depend on appropriate input during this time frame (Hernandez and Ping, 2007). Although critical period effects in L2 learning are still being debated, researchers generally agree that early learning of L2 is associated with higher ultimate proficiency, and age of acquisition is reliably the strongest predictor of ultimate attainment in the language (Birdsong, 2006). Recent developments in the fields of neurolinguistics and neurobiology provide evidence that L2 grammatical processing is carried out through the same brain computational devices as those in L1. Furthermore, proficiency, age of acquisition, and amount of exposure to the L2 has been found to interact in complex ways with the different types of language performance (Perani and Abutalebi, 2005). Interestingly, not only is this true for L2 acquisition but also brain imaging research in neurobiology has revealed a general tendency that early learning (of any type) leads to dedicated neural circuitry that affects the form of cognitive and neural structures at later stages of development (Hernandez and Ping, 2007: p. 646). Moreover, studies have suggested that the attainment of broad native-likeness among late L2 learners is in fact possible (Marinova-Todd, 2003; Hernandez and Ping, 2007; Perani and Abutalebi, 2005). Future research in L2 acquisition must account not only for the typical decline in L2 attainment with age but also for the native-like achievement levels of which some late learners are capable (Birdsong, 2006: p. 37).

The predictive power of the above-mentioned traits, however, has been shown to decrease as the criteria for language proficiency became more communicative and the learning setting became more natural (versus formal and instructional). The most avid pursuit in research occurred in investigations of the role of motivation in learning language and the learner's attitude toward the target language and culture. Using Gardner and Lambert's (1972) differentiation between integrative and instrumental motivation, researchers reported no significant advantage for an integrative (intrinsic) motive and others reported an advantage when the learner was driven by instrumental (extrinsic) motives. Integrative motivation was defined as one in which the target language was being learned by an individual in order to be accepted by the native speaker community. Instrumental motivation was one

in which the language was being learned for external benefits, such as securing a better job.

Results of studies investigating environmental factors reported on the effect on achievement scores. Carroll (1975) conducted a survey of French instruction in eight countries and noted effects on achievement by gender, school type, and teacher gender, and mixed effects according to parental interest. Social factors outside the school were determined to have a significant impact on the development of language proficiency. Both cognitive and affective factors were investigated to explain the variance in foreign language achievement. Motivation, attitudes, anxiety, self-esteem, tolerance of ambiguity, risk-taking, cooperation, and competition proved to be key variables that explained individual differences in foreign language learning (Ellis, 1994). Successful language learning was determined to be largely dependent on who was learning the language, under what circumstances, and for what purposes. Foreign language acquisition was revealed to be a complex, multidimensional process influenced by both learner and environment variables. The questions generated by these theories and research studies began to focus on significant new responsibilities on the part of the teacher in the design and support of individual and personalized learning tasks.

Learning and Measurement

Language teaching has experienced numerous curricular innovations in response to the importance of providing students with opportunities to acquire and practice the foreign language in contextualized and meaningful language communicative tasks at all stages of the second or foreign language acquisition process. Communicative language teaching (CLT), the term most associated with current discussion of method, emerged as a significant approach that found universal resonance and support in theory and application in many contexts and across disciplines (linguists, methodologists, and curriculum developers). Central to the rise of CLT was the realization that linguistic competence does not on its own achieve communicative competence (Canale and Swain, 1980) and that language used in meaningful, authentic contexts is more readily acquired.

Pair work, group work, cooperative/collaborative learning settings, authentic materials, culturally integrated lesson content, and interactive tasks focused on the cognitive and affective domains were integrated into foreign language classrooms. In addition, there has been a call for the reconceptualization of theoretical underpinnings related to use of the target language for language instruction.

Past instructional policies have been dominated by monolingual instructional principles largely unsupported by empirical evidence. In today's multilingual classrooms there is a need to revisit the common assumptions that translation from L2 to L1 (or L3 to L2 for that matter) has no place in the teaching of language or literacy, that instruction should be carried out exclusively in the target language without recourse to students' L1, and that L1 and L2 should be kept rigidly separate (Cummins, 2010). In contrast to these assumptions, recent research has shed light on the fact that the L1 should be seen as a cognitive and linguistic resource that can function as a stepping stone to support more effective performance in the L2 (p. 238).

Furthermore, constructivist teaching practices, influenced by Vygotsky's emphasis on social interaction in learning and development, helped learners to internalize and reshape new information. The theoretical underpinnings of Vygotsky's (1978) view of language learning that maintained contextualized input in cooperative, meaningful interactions with others formed a basis for Sociocultural Theory (SCT), which has enhanced language acquisition and taken hold in classrooms around the globe. According to Lantolf and Pavlenko (1995), the goal of SCT is to understand how people organize and use their mind in the daily process of living. From a sociocultural stance, acquiring language amounts to more than just mastery of the linguistic properties of the L2. It involves the "dialectic interaction of two ways of creating meaning in the world" (p. 110). The interaction between an expert (teacher) and novice (learner) in a problem-solving task (scaffolding) in which the expert's role was to provide the novice with instructional support then became the model for communicative tasks in the foreign language classrooms. Based on Vygotsky's concept of a Zone of Proximal Development (the distance between the actual developmental level and the level of potential development), the expert's and teacher's role was to gain the learner's interest in the task, simplify the task, keep the learner motivated, point out important features, reduce anxiety and frustration during problem solving, and model appropriate form. In accordance with the new responsibilities, the role of the classroom teacher shifted to that of an architect, creating meaningful, interactive, and cooperative learning tasks designed to engage the learner actively in negotiating language meaning in authentic contexts that are co-constructed.

The focus on student language proficiency as measured through performance-based tasks made itself felt both in language learning research and in teaching. Questions emerged regarding how language proficiency could be enhanced and how best to measure the level of language proficiency.

As the proficiency movement has gained momentum in the US and most recently in Europe, consensus was sought about describing and measuring language abilities. The development of the Proficiency Guidelines by the American Council on the Teaching of Foreign Languages (ACTFL) defined what language users are able to do with language in speaking, listening, reading, and writing at various levels of performance. These Guidelines marked a major shift in language pedagogy from methodology to measurement and a focus on learner outcomes. In 1996, content standards were published and subsequently revised (National Standards in Foreign Language Education Project, 1996, 2006, 2014) that delineated what learners should know and be able to do with language. The ACTFL Performance Guidelines for K-12 Learners (ACTFL, 2006) described language performance within three modes of communication (interpersonal, interpretive, and presentational) to assist teachers in understanding how well students demonstrate language ability at various points along the language-learning continuum. A similar effort by the International Association for the Evaluation of Educational Achievement's Language Education Study is seeking a comparison and evaluation of the outcomes of different educational systems across Europe. The Standards Movement, seeking to promote the establishment of guidelines for the teaching of foreign languages for all learners, indicates the growing concern with learner outcomes and accountability.

In a standards-driven environment, the shift to student performance requires that teachers have a repertoire of approaches that target specific goal areas or standards.

Intercultural Competence

Increasingly, language educators contend that foreign language learning should increase students' intercultural competence (IC) which would allow them to see relationships between different cultures, mediate across these cultures, and critically analyze cultures including their own (Chapelle, 2010). Language teachers have now recognized their role in eliciting culture learning in their classrooms and ways to access that learning (Moloney and Harbon, 2010). One such way proposed by Schulz (2007) is through utilization of culture-learning portfolios. According to Schulz, the teaching of intercultural competence should include developing awareness of variables that affect communicative interactions, recognizing stereotypes and evaluating them, and developing awareness of types of causes for cultural misunderstandings between members of different cultures. The use of a culture-learning portfolio allows teachers to assess students' progress over time based on specific objectives that can be related to individual student interest. These portfolios encourage critical reflection and self-evaluation and, especially important in the area of cultural learning, the use of multiple sources of evidence (Schulz, 2007: p. 18). Despite much research into effective strategies and approaches to teaching and assessing intercultural competency in foreign language classrooms (particularly in the United States), several challenges have been put forward. One such challenge is that of sensitizing students to the value of seeing the world through the language/culture of another and creating a more affective climate for developing intercultural competency in an environment where a monolingual monocultural national linguistic identity rules at home and global English rules abroad (Fonseca-Greber, 2010: p. 117).

Foreign Languages: Future Directions

One area that remains controversial in the world of foreign and second language teaching today is the question: Is native-like attainment a necessary or desirable goal in the global world we live in today? In the field of English as a Foreign Language (EFL), the question of whether speakers should conform to native speaker norms of English in light of its increasing use in international contexts has been widely debated in recent years (Timmis, 2002). In light of this issue many scholars in the field have raised the question of why native speaker communities are most often a model for learners of English as an international language. In reaction to this, a deluge of terms have been developed (e.g., Global English, International English, International Standard English, World English, or World Englishes) some of which challenge the idea that only native speaker community varieties are valued (McArthur, 2001). Proponents of the term 'Global Englishes,' for example, promote the idea that English belongs to all who use it, however they use it (p. 4).

Another important direction in research that requires more attention is use and effect of computer technology on foreign language learning. As classroom tasks become more focused on real-world issues, texts, or events, and problem-solving-based tasks, technology introduces a new dimension to the teaching and learning process that incorporates the use of social media such as Facebook, Twitter, Skype, Voice Thread, and others. Digital media allows students to manipulate learning materials and language at their own pace and according to individual needs. Students examine reports, authentic documents, and web pages to find information that can be synthesized and discussed later and can collaborate electronically with youth from around the world. In such a learning environment the role of the teacher changes from one of authority figure or expert who delivers knowledge to one who facilitates, guides, and supports student learning. The teacher assumes greater responsibilities in designing and supporting individual and personalized learning tasks. This has tremendous implications for teacher educators and teacher trainers to act as agents of change as they foster language learning through the use of public pedagogy and critical media literacy. One of the most effective research methodologies that emerged in the last few years has been action research. Inquiring into one's own instructional practices through classroom-based investigations, teachers actively contribute to the research endeavor and change practices based on findings. Such research promises to improve teaching practices that are of interest to both researchers and teachers.

Methodologically classroom-oriented research has been largely conducted within the framework of correlational approaches, case studies, survey research, ethnographic research, experiments, and discourse analysis (Johnson, 1992). While the choice of research method is largely determined by the nature of the research question to be investigated, or by the hypothesis to be tested, thoughtful combinations of qualitative and quantitative research on foreign/second language learning conditions will provide valuable insights into language acquisition processes. Greater use of qualitative and mixed methods investigating students in their classrooms with special attention to cultural, situational, and longitudinal contexts is needed and recommended. As foreign language research draws on related disciplines (psychology, psycholinguistics, neurobiology, neurolinguistics, sociology, and linguistics) to better explain conditions that lead to greater language proficiency and differential success among foreign language learners, a deeper understanding of how languages are acquired and consequently how they should be taught will be gained. Furthermore, as learning and teaching innovations continue to be tested and researched, new insights will be gained that will influence teaching practices globally.

Forensic Archaeology

John J Schultz, University of Central Florida, Orlando, FL, USA

Abstract

Forensic archaeology involves the utilization and adaptation of traditional archaeological methods for locating, documenting, and recovering human remains and associated evidence from a full range of medicolegal scene contexts. While forensic archaeology developed within the field of forensic anthropology, the application of field methods lagged behind the development of forensic anthropology laboratory methods for skeletal identification. However, proper field methods are now routinely used for various contexts involving recoveries of human remains. At the same time, forensic archaeologists routinely improve field methods through research and provide training to law enforcement personnel and various death investigators.

Forensic archaeologists routinely use archaeological field methods when recovering human remains from various medicolegal scene contexts including large mass graves and mass fatality scenes. While this discipline developed within the field of forensic anthropology, the development of laboratory methods for skeletal identification occurred before the development and integration of field methods. However, numerous forensic anthropologists realized that a more comprehensive field recovery was needed as it provided added benefits to the laboratory analysis. Forensic archaeology is now a robust discipline that utilizes and adapts traditional archaeological methods for locating, documenting, and recovering human remains and associated evidence. Furthermore, forensic archaeologists are often involved in improving this discipline through training of law enforcement personnel and research involving improved field methods.

Brief History of Forensic Archaeology

While forensic anthropology has traditionally been a lab-based forensic science, the majority of practicing forensic anthropologists now stress that archaeological methods should be incorporated when recovering human remains. More recently, forensic archaeology has been described as a key development within forensic anthropology (Dirkmaat et al., 2008). However, forensic archaeology methods did not develop at the same pace as laboratory methods for skeletal analysis. The emphasis of incorporating archaeological methods when processing scenes with skeletal remains originated, and was continued, by forensic anthropologists with field experience because they recognized the invaluable contributions that the field component could provide to the skeletal analysis. This initial momentum in applying forensic archaeology methods to process crime scenes involving human skeletal remains and decomposing bodies appears to have begun in the 1970s when a number of publications, including those authored by prominent forensic anthropologists, stressed the important contribution that archeological field methods could provide when processing these scenes (e.g., Morse et al., 1976; Bass and Birkby, 1978; Kerley, 1978; Ubelaker, 1978; Rhine, 1979). These early publications stressed that scene reconstruction involved proper field methods with proper collection and documentation of remains.

While not universally accepted by all forensic anthropologists, forensic archaeology methods were becoming more accepted in the 1980s. These publications included forensic anthropologists and archaeologists emphasizing the application of forensic archaeology field methods as a service that could, and should, be provided to law enforcement and death investigators (e.g., Snow, 1982; Berryman and Lahren, 1984; Wolf, 1986; Brooks and Brooks, 1984; Levine et al., 1984; Morse et al., 1983; Sigler-Eisenberg, 1985). At the same time, the first forensic archaeology manuals were published, which provided step-by-step approaches to proper field methods (Morse et al., 1983; Skinner and Lazenby, 1983). While there were many forensic anthropologists that advocated the use of forensic archaeology methods, Dirkmaat and Cabo (2012) assert that forensic archaeology had remained a peripheral endeavor as the majority of forensic cases received by forensic anthropologists were in a box after the remains were collected by law enforcement, which had not utilized proper archaeological methods.

During the 1990s and 2000s, a large number of important publications (e.g., Connor and Scott, 2001; Dirkmaat and Adovasio, 1997; Haglund, 2001; Haglund et al., 2001; Hoshower, 1998; Scott and Connor, 1997; Skinner et al., 2003; Stover and Ryan, 2001) including additional field manuals in the US and Great Britain (Connor, 2007; Dupras et al., 2006; Hunter et al., 1996; Killam, 1990) discussed why forensic archaeology methods should be implemented for various contexts involving human remains, including human rights investigations. At the same time, forensic anthropology textbooks and manuals started including a more detailed forensic archeology chapter (e.g., Byers, 2002; Burns, 1999). This proliferation of publications is a clear indication that archaeological methods had become accepted within the forensic community. At the same time, investigators also realized the additional benefits of incorporating forensic archaeology methods which included establishing the chain of custody at the beginning of the investigation, providing a more comprehensive trauma analysis, and the reconstruction of past events at the scene (Dirkmaat and Cabo, 2012).

Working in a Medicolegal Context

While traditional archaeology and forensic archaeology both "seek to protect the physical and spatial integrity of potential evidence and remains" (Haglund, 2001: 28), it is important to recognize the differences between the two disciplines. Most importantly, forensic archaeology differs from traditional archaeology because the discipline involves working in a medicolegal context. The forensic archaeologist must be concerned with issues such as rules of evidence, chain of custody, possible court testimony, and their work can be subjected to legal scrutiny (Haglund, 2001). The forensic archaeologist may have a number of constraints when performing recoveries such as foul weather, the media, limited time to perform an excavation for various reasons, and decomposing soft tissues (Schultz and Dupras, 2008; Dupras et al., 2011). For example, the forensic archaeologist may have to perform a recovery regardless of rainy, hot, or cold weather conditions.

Although the field techniques are generally similar between forensic archaeology and traditional archaeology, the recovery goals normally differ (Connor and Scott, 2001). Traditional archaeology is undertaken to answer specific research questions. Conversely, the goal of forensic archaeology is to document the scene and all evidence because it may be useful at a later time. In addition, since forensic archaeologists work under a medicolegal paradigm, rather than an anthropological paradigm, evidence is used to reconstruct single events, and not broad patterns of human behavior (Connor and Scott, 2001). However, the application of proper scene methods allows the forensic archaeologist to understand and interpret the prolonged history of crime scene transformation or change (Skinner et al., 2003). At the same time, it is important to stress that forensic archaeologists must normally adapt and have flexible strategies with their archaeological approach by tailoring archaeological methods for each type of scene (Hoshower, 1998).

Forensic Archaeology Methods

Forensic archaeology methods begin with the search for surface depositions and clandestine graves, and if needed, searches will incorporate multiple methods (Dupras et al., 2011; Schultz and Dupras, 2008). Investigators generally begin with nondestructive methods when searching for surface depositions and clandestine graves to preserve evidence and context of the scene. After nondestructive methods have been exhausted without the success of locating a grave, personnel can then employ a number of destructive methods. At the same time, while nondestructive methods are initially used to locate an area containing a possible grave, a destructive follow-up method is needed to confirm that a grave is actually detected. In addition, while the primary goal of a search is to locate skeletal remains on the ground surface, a clandestine grave, or associated evidence, searches are equally important to clear an area so investigations can be directed to other areas. After the scattered skeleton or grave is located, it is important for the scene to be processed and documented using proper archaeological methods.

Searching for Skeletal Remains Deposited on the Ground Surface

When searching for scattered skeletal remains on the ground surface, searches should be performed in a controlled manner rather than investigators walking over the ground surface without following a particular pattern. At the same time, proper search strategies are used to delineate site boundaries, to locate the primary depositional site, to locate skeletal remains that have been scattered, and to determine the original body position (Dupras et al., 2011; Schultz and Dupras, 2008). Searches normally begin with nondestructive methods such as pedestrian searches and the use of cadaver dogs. For example, a pedestrian search involves personnel searching specific areas while walking side-by-side in a straight line. Larger areas will be divided into more manageable smaller areas that will be searched separately. This search method provides 100% coverage of an area when performed by properly trained personnel. Evidence of a possible body deposited on the ground surface can include a number of characteristics: skeletal remains and soft tissue, clothing and personal objects, decomposition odor, brush or loose trash placed over remains for concealment, animal activity and scavenging, and materials used for wrapping a body (Dupras et al., 2011; Schultz and Dupras, 2008).

Skeletal remains that have been deposited in outdoor environments are most often disarticulated and dispersed due to a number of environmental variables that can include carnivore activity, gravity, human activity, and fluvial (water) transport (Dupras et al., 2011; Schultz and Dupras, 2008). Proper search strategies for locating scattered skeletal remains should consider the method of dispersal. For example, if skeletal elements were scattered because a body was deposited on an incline and skeletal elements traveled downhill because of gravity, investigators should search along the incline and at the bottom of the incline. It is also common for carnivores to disarticulate and scatter skeletal elements. After cleaning the area containing the primary deposit and mapping the visible elements, the forensic archaeologist can perform an inventory of the skeleton to determine the elements that are missing. It may then be possible to locate additional skeletal elements and teeth by determining the pattern of dispersal, which may indicate a direction that carnivores scattered the elements (Dupras et al., 2011; Schultz and Dupras, 2008). Investigators can then begin searching for additional bones along the paths of dispersal and expanding out from those areas.

Searching for a Clandestine Grave

Searches for clandestine graves can be more difficult to locate because a body would have been buried to conceal its location. Personnel should begin searches with nondestructive methods, such as a pedestrian search, by looking for surface features of a grave that are consistent with digging and concealing a body (Dupras et al., 2011; Schultz and Dupras, 2008). A number of common surface features associated with the burial process include excess mounds of soil, or a mounded area, resulting from displacement of soil due to the body. Digging around the grave may be evident because additional soil was needed to cover the body. Soil color changes, with an absence of

vegetation growth, can be noted due to the intermixing of soil horizons comprising different colors. There can also be an increase of vegetation growth in the area of the grave. A primary burial depression, with or without a smaller secondary depression, may occur. It may also be possible to locate a burial from evidence of animal digging and the subsequent disturbance of the remains. In addition, brush piles should also be investigated to determine if brush and tree branches were purposely used to conceal the location of a burial.

Additional nondestructive methods used for detecting a burial include cadaver dogs and geophysical methods. Geophysical surveys are commonly conducted to search for buried bodies and evidence. The majority of geophysical tools used for forensic and archaeological contexts are nondestructive methods that are used to locate and map buried features or objects, such as a grave, without disturbing the ground and scene context. When using a geophysical tool for a search, the application of the method would be used to highlight smaller areas within a much larger search area. These smaller areas would then require limited invasive testing of specific areas, rather than the entire site.

Ground-penetrating radar (GPR) has become the most common geophysical tool used for detection of clandestine graves (Dupras et al., 2011; Schultz, 2007; Schultz and Dupras, 2008) as controlled research has determined it to be the most successful tool used to delineate clandestine graves (France et al., 1997). All of the components of a GPR unit can be cart-mounted and pushed throughout a search area using a grid. The antenna is an interchangeable component, and antenna selection is generally based on soil type and size of the target. The GPR operates by emitting electromagnetic pulses into the ground from the antenna (Dupras et al., 2011; Schultz, 2007; Schultz and Dupras, 2008). As the electromagnetic wave travels through the subsurface, it will be refracted and reflected as it encounters contrasting items and surfaces in the subsurface. The returning wave is then recorded on the monitor of the unit and buried features in the subsurface are recorded as anomalies or reflections. However, these are nonspecific features noted on the imagery that are recognized as a localized area of contrasting properties in the soil. As a result, investigators can sometimes use scene context to determine the origin of a reflection, such as proximity to a tree may indicate detection of tree roots. However, the only reliable method to determine the specific item producing the feature is to perform a destructive follow-up method such as testing the area with a T-bar probe or a shovel test pit. There are drawbacks when using a geophysical tool as scene characteristics such as soil type are a consideration, and clear, flat, and open areas are more desirable for a survey. While the success of a GPR survey is somewhat dependent on scene characteristics, GPR is an optimal search tool when performing a search over a hard-packed surface, such as concrete or pavement, without destruction of the surface as reported by a number of successful case studies (Davenport, 2001; Dupras et al., 2011; Schultz, 2007). When performing this type of search, suspicious areas located under the hard surface by the GPR can be inspected with only minimal destruction.

When nondestructive methods are exhausted during a clandestine grave search without success at locating a grave, investigators may continue searching with a number of destructive methods (Dupras et al., 2011; Schultz and Dupras, 2008). Common methods include a grid search using either a T-bar probe or shovel test pits. For example, a T-bar probe is pushed into the ground to detect areas comprising less compact soil associated with digging a grave. Investigators will incorporate a T-bar probe to highlight smaller areas for follow-up testing. Once these smaller areas are located, investigators can further investigate the follow-up areas using shovel shining. This method involves scraping away the soil to discern soil changes associated with digging that could indicate a grave. Finally, when all of these search methods are exhausted, a forensic backhoe, with a flat-toothed blade, may be the last option to clear an area or locate a grave. When operated properly, the backhoe is used in the same fashion as shovel shining to discern evidence of disturbed soil that could indicate a possible grave.

Recovering and Excavating Human Remains

Since processing a scene is a destructive endeavor, the ultimate goals are to document scene context, to reconstruct prior events, or behavior, and to recover evidence properly (Dupras et al., 2011; Schultz and Dupras, 2008). To achieve these goals, the forensic archaeologist must perform a recovery or excavation that utilizes proper methods. Scene documentation first includes note taking that is continued throughout the entire recovery process. While scene photographs should be taken to document the entire process, photographs should also be taken to document the terrain of the surrounding area. In addition, all evidence and bones must be mapped to record the spatial location of this material.

When presented with a surface recovery of a skeleton in a wooded area, investigators should not begin by immediately removing bones without any documentation method. The visible bones and surrounding area should first be cleaned of leaf litter to expose the ground surface along with the skeletal elements and evidence. Prior to physically removing the bones, investigators should record the scene using notes, photographs, and a mapping method that involves recording the special location of all bones and evidence. The bones and evidence should be removed carefully to limit any postmortem damage, and then the material should be placed in labeled bags using a notation system that allows investigators to reconstruct the exact scene location for all of the evidence and bones. The forensic archaeologist would then scrape the ground surface with a trowel and then screen the removed soil to make sure all of the evidence and bones were recovered. In addition, if the skeleton was scattered, they would formulate a strategy to search for additional bones. The recovery will also consist of collecting additional scene evidence, such as entomological and botanical, that can be used to assist with time since death. The detailed recording of scene information can then be used to reconstruct the scene, which will include detailed maps.

Applications of Forensic Archaeology

Forensic archaeology methods are routinely used in various contexts when recovering human remains. While forensic archaeologists are commonly involved in the recovery of

remains, usually involving single individuals, for law enforcement agencies, medical examiners, and coroners, they are also involved in other recoveries that can pose additional challenges. A number of the noteworthy examples include the recovery of the US serviceman listed as missing in action (MIA) or prisoners of war (POW) from previous conflicts, processing mass fatality incidents (MFIs), and the excavation of mass graves involving victims of human rights abuses.

Joint POW/MIA Accounting Command

An important military organization that utilizes forensic archaeology is the Joint POW/MIA Accounting Command (JPAC). This organization is operated through the Department of Defense and is the largest forensic skeletal identification laboratory in the world (Holland et al., 2008). The headquarters and the Central Identification Laboratory (CIL) are located near Honolulu, Hawaii at the Joint Base Pearl Harbor-Hickam. The mission of JPAC is "to achieve the fullest possible accounting of the US service personnel missing from past wars and conflicts" (Holland et al., 2008: 47). In order to achieve this mission, JPAC regularly conducts missions to areas of prior conflicts throughout the world utilizing a mix of archaeological principles and crime scene investigation procedures to locate and recover the remains of missing US service personnel. Since 1976, JPAC and its predecessor organization Central Identification Laboratory Hawaii (CILHI) have performed recoveries in over 40 countries representing different types of terrain such as the jungles of South America and Southeast Asia, the Himalayan Mountains of Tibet, the Mediterranean Sea, the frozen tundra of Siberia, the beaches of the Solomon Islands, and the desserts of Iraq (Holland et al., 2008).

According to Holland et al. (2008), the identification process begins with the field recovery that includes a team of 12–14 personnel. Team members also include military personnel, a medic, a linguist, as well as specialists in explosive-ordinance disposal, photography, aircraft evidence analysis, and communications. The recovery leader of the team is normally a civilian anthropologist who is trained in human osteology, archaeological techniques, and evidence-handling techniques. The field recovery involves three stages: research and analysis, investigation, and recovery (Emanovsky and Belcher, 2012). Research and analysis include a historical overview of records to identify possible cases for field investigation. The investigation stage involves trying to correlate the exact location of a specific loss incident and traveling to the area to perform an investigation. Cases are then selected for recovery based on the probability of locating remains. Upon completion of a mission, all recovered remains of service personnel and material evidence are brought to the JPAC-CIL for analysis and identification by forensic anthropologists.

Mass Fatality Incident

In recent years, forensic archaeology methods have become standard practice when processing MFIs. Since September 2001, many jurisdictions have been preparing for a wide range of disaster scenarios (Dirkmaat, 2012). At the same time, investigators may revisit prior mass disaster scenes to implement continued search strategies for remains of victims. For example, when human remains were unexpectedly located near the World Trade Center (WTC) site in New York City in 2006, the Office of Chief Medical Examiner renewed efforts to locate additional remains of potential victims (Rainwater et al., 2008). The goals of the renewed efforts were to "identify the boundaries of the WTC debris deposits, excavate and document all material that may contain WTC victims' remains and personal effects in a continued effort to identify victims" (Rainwater et al., 2008: 562).

One of the most important forensic archaeology contributions for MFIs occurred in the field recovery protocol of airplane crashes. Mass fatality scenes had historically involved random searches over a few days, usually along paths of least resistance, to flag the largest items that would be collected after a few days without noting the provenience of the recovered items (Dirkmaat, 2012). The search for human remains would continue again to locate any remains not discovered during the initial search, while not noting provenience of the remains. According to Dirkmaat (2012), this inefficient method of processing the scene of an aircraft crash was the result of not considering the scene as a crime scene because all of the individuals died of a catastrophic event. Eventually, processing of the scene would end after a couple of weeks, because it was believed that additional human tissue could not be used to identify the individual.

It was finally recognized in the early 2000s that this inefficient processing method needed to change because DNA was now being used to regularly identify fragmented remains, including small fragments, and that criminal intent, particularly through terrorism, could result in MFIs (Dirkmaat, 2012). In the late 1990s, Dirkmaat and colleagues developed and implemented large-scale scene processing recovery protocols to be used at MFI scenes such as airplane crashes (Dirkmaat, 2012). These protocols involved straight-line searches through the crash site, where personnel would flag all significant evidence (human remains, personal effects, and identifiable plane parts). A second team would then document and map the location of the evidence prior to the collection phase. Overall, advantages of implementing these forensic archaeology protocols when processing a mass disaster scene include 100% search coverage of the ground surface, provenience and chain of custody is maintained for all recovered evidence, and the proper reconstruction of crash dynamics (Dirkmaat, 2012).

Human Rights and Mass Graves

Forensic archaeologists are important team members in the search, recovery, and identification of victims of human rights violations around the world (e.g., Latin America, Croatia, Bosnia, East Timor, Iraq, Rwanda, and the former Yugoslavia). Archaeologists have been recruited, along with numerous other forensic experts, by the United Nations and human rights organizations (e.g., Physicians for Human Rights) to excavate the individual and mass graves associated with investigations of war crimes, genocide, and political killings (Stover and Ryan, 2001). The history of properly recovering and analyzing human rights victims began when noted forensic anthropologist Clyde Snow was asked to recruit a qualified forensic team to assist with exhumations and identifications of individuals that died during the Argentinian Dirty War (Doretti and Snow,

2009). Applying techniques from forensic archaeology and anthropology, Snow's team conducted exhumations using proper field and laboratory methods. Snow retuned to Argentina many times between 1985 and 1990 to train and work with the team that was formally organized as the Argentine Forensic Anthropology Team in 1986.

The majority of methods used to excavate mass graves were developed in standard archaeological practices and applied to contemporary mass graves (Tuller, 2012). The forensic archaeologist is involved in determining the location of a grave, the delineation of the grave, the excavation of the grave, and body removal (Haglund et al., 2001). While witness testimony is the most successful method for locating graves (Haglund et al., 2001), the forensic anthropologist working in human rights investigations may also be involved in interviewing witnesses (Tuller, 2012). Once a grave is located, the archaeologists will need to confirm or deny the presence of a grave using standard archaeological methods, including geophysics (Tuller, 2012). At the same time, it may be necessary to delineate the horizontal extent and amount of overburden of large mass graves with tens or hundreds of bodies prior to determining an appropriate excavation strategy (Haglund et al., 2001).

More recently, mass grave excavations have focused on collection of evidence to assist with cause of death and an understanding of site formation processes (Skinner et al., 2003). In order to reconstruct the events at a site before, during, and after the creation of a mass grave, the excavation should be conducted to determine the order, or depositional events, that made the graves, as each depositional event should be present as distinct strata (Tuller, 2012). Furthermore, proper documentation of each article of evidence is essential during the excavation of a mass grave as this information can be important in linking evidence from multiple sites (Tuller, 2012). For example, linking evidence can be used to confirm that perpetrators were acting in an organized manner on specific orders from superiors, or acting independently.

Forensic Archaeology Training

Personnel trained in forensic archaeology methods may also be involved in training and research associated with this endeavor. Many forensic archaeologists routinely provide training lectures to death investigation personnel. They will lecture on various topics that can range from a general overview of forensic archaeology or anthropology, more specific archaeological methods such as the application of geophysical methods, nontraditional searches, and they will normally include case studies. This generally occurs when they are invited by a death investigation organization (i.e., law enforcement agency) to provide a lecture about forensic archaeology that normally is 1 or 2 h in duration. In addition, there are a variety of forensic archaeology short courses available in the United States for death investigation personnel to learn basic forensic archaeology techniques. More recently, forensic archaeology training courses are available for learning protocols for processing an MFI scene (Dirkmaat, 2012). Death investigation personnel normally attend these lectures as continuing education training required for their employment. These courses are designed to provide participants with proper search, excavation, mapping, and documentation techniques, as well as collection and proper packaging methods (Dupras et al., 2011; Schultz, 2007; Schultz and Dupras, 2008). In addition, participants are taught how to recognize, collect, and preserve different classes of associated evidence such as botanical, entomological, and soil samples.

The participants learn the various archaeological methods through a number of mock scenarios devised by the instructors. For example, one common scenario includes scattering a skeleton and associated evidence over a moderately large area. Participants would then learn the proper methods that are first needed to locate all of the skeletal elements such as performing a pedestrian line search and visually looking for the individual bones. After they locate and mark the location of all of the bones and associated evidence, they would then learn how to map the scattered skeleton and properly document and collect the bones and associated evidence. Another common mock exercise for the participants is to learn the methods for excavating a grave. The graves will commonly contain a plastic human skeleton or animal carcass such as a pig (*Sus scrofa*). Part of the exercise may first include trying to locate the grave by recognizing ground surface characteristics. Once the grave is located, participants will learn how to set up an archaeological grid that is used to maintain spacial controls before performing the actual excavation.

Forensic Archaeology Research

Research has been instrumental in improving and integrating traditional archaeology methods to forensic contexts. In particular, research focusing on various technologies used to search for graves and mapping scenes must be undertaken to understand how these technologies can be integrated as part of the multidisciplinary protocol. For example, controlled research has been instrumental in understanding how geophysical technologies such as GPR could be implemented for clandestine grave searches (France et al., 1997; Schultz, 2008; Schultz et al., 2006; Schultz and Martin, 2011, 2012). Researchers commonly devise a number of grave scenarios using pig carcasses as proxies for human bodies. They then control a number of variables such as carcass size, grave depth, soil type, length of internment, and possibly scenario type. While the research provides experience to the personnel, it also allows them to make predictions concerning grave detection during actual forensic GPR searches.

More recently, forensic archaeology research has explored the use of mapping different scenes using a differential global positioning system and analyzing the scatter with global information systems. This research involves devising a number of different surface deposition scenarios in open and obstructed environments (Walter and Schultz, 2013). The scenarios were then mapped and the degree of scatter was analyzed based on the type of scenario. Overall, recommendations were provided for integrating this mapping technique based on scene variables when recovering a scattered skeleton.

Forensic Genetic Databases: Ethical and Social Dimensions

Barbara Prainsack, King's College London, London, UK

Abstract

This article starts with a brief summary of the origins of forensic genetic profiling and databasing. It then provides a typology of forensic genetic databases and discusses key societal and ethical issues related to different configurations of forensic genetic databases across countries. It concludes with an overview of the most current ethical and societal concerns related to DNA databasing in the context of criminal investigation and criminal justice.

Background: The Beginning of Forensic Genetic Profiling

Forensic genetic databases are important tools for criminal investigation and criminal justice in many countries across the globe (Hindmarsh and Prainsack, 2010; Krimsky and Simoncelli, 2011). An answer to the question of when the history of forensic genetic databases began is not a straightforward one. Most official histories of forensic genetic *profiling* (not databasing as such) start with a discovery that geneticist Sir Alec Jeffreys made in his lab in Leicester, England, in 1984: After finding regions of the mammalian genome that had a particularly high degree of length variability (due to the presence of differing numbers of short, repetitive sequences of DNA), Jeffreys and his colleagues decided to find out whether similar variations could also be found in the human genome. Preliminary experiments revealed not only the existence of these polymorphisms (i.e., variations in length) in humans, but also that patterns tended to be inherited in a regular fashion. The more distant the genetic relationships among family members, the fewer similarities their DNA profiles displayed on average; the closer the genetic relationships, the more similarities in their DNA profiles. In cases of monozygotic twins and multiples (who share virtually 100% of their DNA), as well as in cases where two DNA profiles come from *the same person*, all the markers seen in the DNA profile are identical.

Jeffreys called his discovery DNA fingerprinting in order to borrow some of the legal and social credibility of its namesake 'regular' fingerprinting (dactyloscopy) (Lynch et al., 2008). This new technique, as well as refinements of the basic idea made by researchers around the world, rendered possible the comparison of people's genetic makeup to establish whether two (or more) DNA profiles came from the same person. This, in turn, enabled criminal investigators to link particular people to particular crime scenes (e.g., if, through comparison of DNA profiles, it was found that a person's DNA profile matched that of a biological trace found at a crime scene).

Despite this effort to establish DNA analysis as a reliable form of evidence, the use of DNA technologies in criminal investigations and in the courtroom was highly contested; experts and practitioners engaged in heated discussions about the scientific robustness and reliability of the technology, as well as about various issues concerning the probability that specific DNA variants or even entire profiles might be shared by two different individuals (Aronson, 2007; Lynch et al., 2008; Kaye, 2013). These controversies are now referred to as the 'DNA wars'; they were *de facto*, if not in principle, resolved in the course of the 1990s, when experts moved on from discussing whether DNA technologies were fit to be used as evidence at all to which tools and methodologies were most robust in the criminal justice context and what regulatory mechanisms needed to be put into place to ensure their validity and reliability.

How Does Forensic Genetic Profiling Work?

In contrast to fingerprints, which are recorded in the form of (annotated) visual data, information from modern polymerase chain reaction-based DNA profiling techniques is recorded as sets of discrete, numerical data (specifically, the size of a particular DNA fragment). When we look at a predefined set of specific places on the genome, we find that different people have different numbers of so-called short tandem repeats (STRs) in these places. Like the variant regions of the genome that Jeffreys focused on, STRs are repetitions of chains of nucleotides (nucleotides make up DNA). The greater the number of such places (loci) on the genome that are analyzed, the smaller the likelihood that two different people *coincidentally* have the same number of repetitions in all places. The chance that two people do have the same number of repetitions in the same places – the so-called random-match probability – increases not only when fewer loci are analyzed, but also when the number of repeats in a certain locus are relatively common in the respective population (in other words, when they are fairly typical for this population) or when individuals are biologically related. For example, full siblings share 50% of their DNA, on average. This means that on average, half of the genetic information (number of repeats) in the loci that forensic tests analyze will be the same. This phenomenon is utilized in a technique called familial searching. This method assumes profiles that match in many but not all loci are an indication that the real perpetrator could be a biological relative of the person whose profile produced the partial match (Murphy, 2010; Kaye, 2013; *see* Genetics and Forensics).

The basic underlying principle of STR-based genetic analysis is thus one of stratification – of assigning people to different

groups according to their genetic markers – and not of absolute individualization (Amorim, 2010). This is an important caveat with respect to this technology and an important difference from fingerprinting, for example, when we assume that fingerprints are indeed unique for every individual. (It should be noted that the reliability of fingerprint analysis is being challenged increasingly, partly as a result of the emergence of DNA profiling as the gold standard of good forensic science. The problem here, however, lies with methods and practices of comparison and not with the uniqueness – or lack thereof – of individual fingerprints; Cole, 2001; Dror and Mnookin, 2010; Mnookin et al., 2011.)

Despite the probabilistic nature of DNA profiles, they are often treated in criminal justice as if they could be unambiguously linked to one person. There are two main reasons for this. The first reason is that although the results of a DNA profile comparison are always probabilistic and never certain, random-match probabilities (the chance that a profile matches a randomly drawn profile) are often so high that they become forensically irrelevant. For example, in the context of the world population's currently being just under 7 billion, if we were faced with a random-match probability of a given profile of 1:10 trillion, it would be practically (albeit not statistically) impossible that the DNA profile had not come from the originator of the matching profile (provided that there were no issues with the preservation and analysis of the profile, such as contamination, etc.; see below). The second reason for DNA profiles' being treated as if they allowed for the establishment of a certain link between a person and a profile is a phenomenon that has been referred to as the Crime Scene Investigation (CSI) effect. This label captures, broadly speaking, the notion that the wide popularity of technocentric television drama – series in which the main heroes are not people, but technologies – has shaped our perception of what forensic technologies can and should do. The CSI effect has taken its name from the widely popular US series 'Crime Scene Investigation.' It does not apply only to members of the public but also to actors within the criminal justice system, such as jurors and judges (e.g., Cole and Dioso-Villa, 2007, 2009; Kim et al., 2009) and even prisoners (Machado and Prainsack, 2012).

Forensic Genetic Databases: The International Landscape

For much of the first decade after its introduction into criminal investigation in the 1980s, DNA profiling was used strictly on a case-by-case basis. This means that DNA samples were taken from crime scenes and suspects for specific investigations, but DNA profiles were typically not stored in a central database. The first central forensic genetic database was set up in England and Wales in 1994, with countries such as the Netherlands (1997), Austria (1997), and Germany (1998) following suit. Other countries in Europe (e.g., Italy, Greece, Malta, and Ireland) as well as many countries outside of Europe (e.g., many African countries) at this time early in 2013 still did not have centralized forensic DNA databases. In the United States, a system for the archiving and comparing DNA profiles was launched as a pilot program between the Federal Bureau of Investigation (FBI) and a subset of state and local laboratories in 1990 (Combined DNA Index System; CODIS), was enabled at the national level by the DNA Identification Act of 1994 and formally came into existence in October 1998 (Aronson, 2010). Unlike the databases in many other countries, the FBI is not responsible for physically uploading to or maintaining profiles on the database. Rather, it enables connectivity among a collection of databases controlled by state and local law-enforcement agencies. Decisions about what offenses are worthy of inclusion in the database are determined by state legislatures, not the U.S. federal government, and although the FBI issues requirements for the laboratories that participate in CODIS, it does not fully regulate or control them. CODIS allows investigators in one jurisdiction to look for matches in the databases in jurisdictions other than their own. The CODIS database started out as a repository of DNA profiles of convicted sex offenders; it became more expansive over time and now includes profiles of various types of convicted offenders and suspects, depending on provisions at state levels. Some states restrict inclusion criteria to serious felonies, but others allow inclusion of misdemeanors and even arrests. Today, CODIS stores profiles of more than 5 million people, that is, about 1.5% of the nation's total population. In terms of the absolute number of profiles stored, it is the largest DNA database in the world.

Within the European Union, the so-called Prüm Decision (2008) required EU member countries that had not already established centralized forensic databases to set them up by August 2011 in order to allow authorized actors in law enforcement in each country to search for DNA profile matches across DNA databases in the whole of the EU. The Prüm Decision, although supported by countries such Germany, Austria, and the Netherlands, faced considerable resistance from other countries such as the United Kingdom (closer to production date: update whether the UK has opted out of pre-Lisbon acquis); and some countries did not make the 2011 deadline due to financial or political struggles (Prainsack and Toom, 2013). Although the Prüm Decision is binding for EU member countries only, (unless they have opted out) some of the substantive provisions of the decision are mirrored in bilateral treaties signed between the United States and individual European countries (at the time of writing this article, these bilateral treaties focused mostly on the exchange of fingerprints; yet they were devised in such a way as to allow them to be extended to the exchange of DNA profiles by signing an additional protocol).

Infrastructures for the transnational exchange of forensic bioinformation (DNA and fingerprints), however, predate the Prüm regime. Interpol has been providing an infrastructure for forensic DNA data exchange internationally since 2003. Every member country of Interpol hosts a national Interpol contact point where dedicated matching software is installed on a separate computer system. No nominal data (names, addresses, etc., of existing persons) are included in the system, nor is it connected to any other forensic information network. Member countries can define which countries they do and do not want to compare data with. The rationale for excluding some countries from the range of those that a particular country compares profiles with can be underpinned by concerns regarding how that other country runs the database, or it can be underpinned by purely practical considerations

(e.g., European countries that have already ratified the Prüm regime compare their data only via the Prüm network and thus exclude each other in the list of countries with which they exchange data via the Interpol DNA Gateway). Whether individual member countries respond to queries from other countries by checking whether the profile matches any profiles in their own databases is up to them, and response rates vary considerably across countries. Although the Interpol DNA Gateway stores the DNA profiles that member countries upload to it in a central system, it was never meant to replace national DNA databases; its role is to provide a complementary structure dedicated to the exchange of profiles across borders. Although the Interpol DNA Gateway shares this latter goal with the Prüm regime, an important difference between the two – besides the international vs European remit and the degree of automatization of the comparison – is that the Prüm system is not a physical database at all; it is merely a mechanism allowing mutual access to the database of EU member countries (i.e., member countries technically search certain elements of each other's databases directly (Prainsack, 2010)).

A Typology of Forensic DNA Databases

There is no universal set of criteria according to which forensic genetic databases in different countries are organized. There are, however, certain dimensions that can help us to understand some core differences and similarities (see **Table 1**).

The first of such dimensions are the criteria for profile inclusion. Some countries (and American states) include in their forensic genetic databases only DNA profiles of convicted offenders or also of suspects of serious offenses (for the latter group, in some countries profiles are removed from the database by authorities if these suspects are not convicted later; for more details, see Hindmarsh and Prainsack, 2010). The underlying rationale for this restrictive approach toward profile inclusion is often a combination of two assumptions on the side of the authorities: The first assumption is that it is mostly a particular subset of the population that commits crimes and that including a wide range of people, or even the entire population, in the DNA database would increase the administrative burden without significantly increasing detection and conviction rates. The second assumption is that most members of the public do not like the idea of having their DNA profiles stored in any centralized database under governmental control and that, therefore, storing profiles of convicted offenders only or of suspects of serious crimes represents a good compromise. Other databases, such as the National DNA Database (NDNAD) in England and Wales, allow for the additional inclusion of profiles of people who have committed very minor offenses or who were arrested but never charged or were later acquitted. In the United States, the DNA Fingerprinting Act of 2005 allows the federal government to include the profiles of all persons arrested for federal crimes as well as all non-U.S. detainees. The last category is, of course, directly relevant to the American war on terror. Another major issue in the United States is that state and local authorities often keep a non-CODIS (offline) database with wider inclusion criteria that they use for local investigations.

Table 1 Central dimensions of a typology of forensic genetic databases

Classification criteria	*Features*
1. Profile inclusion criteria	Restrictive/expansive
2. Profile retention criteria	Restrictive/expansive
3. Sample retention	Yes/no
4. Genetic markers tested	Dependent on type of chip and software used (e.g., Next Generation Multiplex: NGM, CODIS)
5. Tendency toward expansion, function creep	Yes/no (and how exactly)
6. Responsibility for, and custody of, the database	Police/judiciary
7. Profiles come from	Labs run by the government/private labs/mixed systems

A second, related dimension is the criteria for the retention of DNA profiles. In some jurisdictions such as, again, England and Wales, once somebody's DNA profile has been included in the central forensic DNA database, it can stay there indefinitely. Such an expansive approach toward profile retention is typically underpinned by the assumption that people who start out by committing small offenses often 'mature' toward committing more serious crimes, and thus, having their DNA stored in the database can help to increase detection rates later on. Moreover, legal provisions stipulating that profiles must be removed from the database a certain number of years after inclusion – provided that the profile's originator has not been found to have committed any offenses or crimes in that period, or when the originator has reached a certain age – always imply a duty on the side of the relevant authorities to actually remove the DNA profiles. This is often logistically difficult, especially against the backdrop of scarce human and financial resources.

A result of the coexistence of restrictive and expansive profile inclusion and retention criteria is that the proportion of a country's (or state's) population that has DNA profiles stored in a database for police and forensic purposes varies widely. At the end of 2012, the NDNAD in England and Wales had stored DNA profiles from the greatest proportion of their total population – roughly 10%. (These percentages can change fast when the inclusion and retention criteria in a country change.) Also, although most countries and states include predominantly profiles of convicted offenders, others also include profiles of mere arrestees (who were not charged or not convicted) as well as profiles of other groups, such as victims and volunteers; the latter two groups are included to enable profiles from crime scenes to be excluded from the investigation. For example, if several DNA samples are taken at a crime scene, it can happen that some of the samples taken stem from people who are not suspects, i.e., the victims' family members, friends, or neighbors, etc. Profiles of these people are often collected – and in some countries, included in the database – to make sure that the police do not waste time investigating leads coming from DNA profile matches that are unlikely to have come from the suspect(s).

A third dimension in the classification of forensic genetic databases is sample retention. A DNA sample is the physical biological matter – e.g., a blood or semen stain, a trace of saliva,

etc. – that a DNA profile is derived from. DNA samples are never, as such, included in the dabatases (only profiles are), but practices vary greatly among countries regarding the storage of DNA samples. Some countries, such as Germany and at least one US state, Wisconsin, destroy samples as soon as the DNA profile has been derived from it; many others, including most US states, store the samples. Especially the retention of so-called subject samples – that is, samples that were not collected at crime scenes but that were taken by means of a buccal swabs from certain groups of people, such as convicts, suspects, arrestees and, in some countries, also volunteers and even victims – has attracted a great deal of concern. Critics of subject sample retention are worried that stored samples could be used for more wide-ranging genetic analysis; for example, the samples could be searched for markers that disclose information about genetic predispositions to diseases or personality traits (which is not possible to infer from the information contained in a traditional DNA profile stored in the DNA database). Many of those who support sample retention, in contrast, hold that this practice poses relatively few additional privacy risks and that it has considerable practical advantages, for example, for EU countries in the context of the aforementioned Prüm regime. Here, certain kinds of preliminary DNA matches need to be confirmed by an additional DNA analysis (because the Prüm regime treats certain kinds of mismatches as matches in the first instance). If the sample has not been retained, the police would need to find the originator of the DNA profile and obtain another sample, both of which may not always be feasible.

A fourth dimension in our typology pertains to the set of markers included in a forensic DNA profile. Not all countries include the same set of markers in the DNA profiles stored in their databases. In Europe, the so-called European Standard Set (ESS) of loci was endorsed by the European Council in 2001. The ESS is a minimal consensus of markers that all EU countries are encouraged to include in their DNA profiles to allow comparison across countries, regardless of the particular chip and software they use for sample analysis and profile storage. In the second half of the early 2000s, the European DNA Profiling Group, an association of forensic scientists, proposed the addition of five, new STR loci to the ESS (Gill et al., 2006) in order to enhance the discriminating power of DNA profile comparisons. The EU Council enforced this in a Council Resolution in 2009. In the United States, plans to increase the CODIS markers from 13 to 24 (Hares, 2012) were still under discussion at the time of this writing. Interpol, because of its role as facilitator of bioinformation exchange for police and forensic purposes internationally, has developed a minimal consensus set of seven loci that are included in most databases in the world (the so-called Interpol Standard Set of Loci (ISSOL)). The five new ESS markers are now being added to the existing seven ISSOL, so that Interpol effectively uses 12 loci for transnational DNA profile comparisons.

A fifth dimension pertains to whether a database is showing a tendency toward expansion. Such a tendency can manifest itself in a trend toward becoming more inclusive of the kinds of profiles that are stored and/or retained in the national DNA database, e.g., in the Netherlands (Toom, 2012) and in New York State's 2012 decision to include profiles of all convicts, irrespective of whether the crime was mass murder or a minor misdemeanor, in its state database (New York State Division of Criminal Justice Services, 2012). Expansion can also occur in the functions for which DNA samples or DNA profiles are being used. This latter phenomenon of expanding the functions and purposes of samples and profiles has been referred to as function creep (e.g., Dahl and Sætnan, 2009). In some instances, the functions and purposes of materials initially collected and analyzed in connection with a forensic genetic database become so widely extended that they are no longer limited to the original functions of the DNA database. The aforementioned method of familial searching is an example of function creep. Familial searching, also known as genetic proximity testing, can be performed if a DNA profile derived from a crime scene stain results in a partial match with a profile in the database. Police could then apprehend the person identified and investigate whether she or he has any biological relatives who could have committed the crime (Bieber et al., 2006; Greely et al., 2006; http://www.denverda.org/DNA/Familial_DNA_Database_Searches.htm). Genetic proximity testing can be seen as function creep because it adds an additional feature to the existing functions in forensic DNA databases and consequently broadens the scope of individuals who are likely to be targeted by police investigations (*see* Genetics and Forensics).

Function creep can also occur when databases become increasingly interlinked. In the European context, the aforementioned Prüm Decision is the most important example. A concern related to the large number of profiles stored in such database networks is that the chance of false-positive matches increases as well.

A sixth dimension relevant to classifying forensic genetic databases is this question: in whose jurisdiction and under whose control does a forensic DNA database exist? In some countries, the database lies within the authority of the judiciary, whereas in others it is run by police authorities.

The seventh and final dimension relates to the kinds of laboratories that carry out the genetic analyses (i.e., who derives the profiles from the DNA samples that are then uploaded to the database). In some countries, law enforcement authorities operate their own labs for this purpose. In other countries, private or university labs that are properly accredited also can provide DNA profiles for inclusion in the DNA database. In the United States, public and private labs coexist. In Great Britain, due to the recent closure of the Forensic Science Service, DNA profiling has been almost entirely privatized – in keeping with the notion of austerity promoted by that country's coalition government.

Ethical and Societal Concerns about Forensic Genetic Databasing

DNA databases are not foolproof producers of truth. Along with the fact that, as discussed above, DNA profiling per se does not produce certain but only probabilistic links between profiles, there are challenges to be met at every stage of the process, from securing a DNA trace at a crime scene to presenting DNA evidence in court.

At the stage of securing traces at a crime scene, insufficient resources and inadequate training of scene-of-crime officers

can cause problems, such as overlooking potentially usefully evidence or causing contamination. Contamination occurs when a DNA sample is accidentally mixed with somebody else's DNA – such as the scene-of-crime officer's, the perpetrator's, or a victim's – without there being a record that this has happened (sometimes crime labs analyze traces from crime scenes when it is known that the traces contain DNA from more than one subject, e.g., from the victim and the perpetrator; such mixed traces are not instances of contamination). The risk of contamination can be minimized but never eliminated entirely, and it can happen also in light of very high standards. Contamination can also take place in locations other than the crime scene, e.g., during transportation or storage: Samples could be swapped, misplaced, or deliberately tampered with.

Once a sample has arrived at an accredited crime lab, the risk for contamination should in theory be very low because all accredited labs are obliged to have mechanisms in place to avoid contamination. (It should be noted, however, that not all labs in which DNA analyses for police or forensic purposes are carried out have accreditation.) Such mechanisms include, depending on the lab, electronic tagging, videotaping, or using different facilities for the analysis of samples from victims and those from suspects. Once lab workers have derived a DNA profile, it is uploaded to the central DNA database.

We have already discussed issues involved in the calculation of random-match probabilities in the course of profile matching. A growing problem is that although forensic scientists and those running DNA databases are usually well aware of what a DNA profile match can tell us about a case and what it cannot, other actors in the criminal justice system are often less aware of such limitations. Because not only many members of the public, but also many judges and jurors, regard DNA science as infallible, numerical interpretations of DNA evidence are often taken as facts (related to this is also the aforementioned CSI effect). Another problem pertaining to using DNA evidence in court is the so-called prosecutor's fallacy in assessing the probabilities of guilt or innocence of a suspect based on the presentation of forensic evidence. For example, the expert witness in a case could state that the chance that a DNA obtained from the crime scene randomly matches somebody other than the defendant's is one in one billion. In that case, the prosecutor's fallacy would be to misinterpret this to mean that the chances that the defendant is innocent are one in one billion. This, of course, is incorrect, because even if it could be established with certainty that the DNA from the crime scene was indeed the defendant's, that would not prove that the defendant committed the crime: her or his DNA could have been at the crime scene for legitimate reasons, or it could have been planted, or the sample could have been contaminated at some stage with the defendant's DNA. Obviously, such misunderstandings could have disastrous consequences for the defendant. The term defense attorney's fallacy is used to describe the opposite scenario. In light of a random-match probability of, for example, one in one million, some defense attorneys argue that in a city of 8 million inhabitants (half of whom can be assumed to be of the same sex as the defendant), there are four other people who could be the originator of the DNA. This is false conclusion because it ignores all other circumstances of the crime (e.g., not all 4 million other people had access to the crime scene; some of these 4 million may be young children, etc.).

Overarching Societal and Ethical Issues

In sum, although there is wide agreement that DNA databases are a very helpful tool in criminal investigation and criminal justice more broadly, it is important to be aware of their limitations. Besides the limitations inherent in the (STR-based matching) technology itself, namely, that it produces only probabilistic results and that it is impossible to abolish entirely the risk for contamination, there are some overarching societal and ethical issues related to DNA databases for police and forensic purposes. An important one is the issue of the over-representation of certain population groups. On the basis of known issues concerning racial discrimination in arresting, charging, and sentencing, it is plausible to assume that this over-representation of some minorities is, at least in part, due to such discriminatory practices on the side of law enforcement and state authorities (Kaye, 2013). In the United States, for example, there are significant racial disparities at all levels of the criminal justice system, from the likelihood of being arrested and convicted of a crime, to sentencing, and to representation in the prison population (Duster, 2004). African Americans and Hispanics are the most highly at risk in these contexts (arrest rates are more than six times higher for blacks and Hispanics than for whites), suggesting that these minority populations will soon be over-represented in CODIS as well. It should also be kept in mind in this context that behaviors that are more prevalent among underprivileged groups are more prone to being criminalized (Washington, 2010). Also for this reason, forensic genetic databases are seen to exacerbate existing ethnic and socioeconomic biases, particularly in the context of familial searching. In this case, the high prevalence of minorities and the poor in the database may increase the likelihood that a poor person or a person of color who commits a crime is found through the DNA of their close relatives. In the context of the United States, Levine et al., (2008) worry that CODIS may soon become 'Jim Crow's database' (i.e., may represent an instance of *de facto* racial segregation). Some experts (including Alec Jeffreys) have argued in favor of universal DNA databases that include profiles of every citizen, or even every resident, of a country. No country has implemented this solution yet, although some have considered it (such as Portugal, for example).

A further issue is that we have no solid data concerning the effectiveness of DNA databases. DNA evidence is rarely used in isolation; in criminal investigations and in court, other kinds of evidence, such as witness testimonials and findings from other forensic analyses (finger- or footprints, toolmarks, etc.), are typically considered in conjunction with DNA evidence. Thus it practically impossible to measure the effects that DNA analysis and DNA evidence alone have had on an investigation or a trial. As a consequence, critics of (the expansion of) forensic DNA databases argue that our assumption that this is an effective tool for criminal justice is based on ideology rather than hard evidence. Critics also contend that the channeling of resources into DNA databases

contributes to the technologization of policing, where values such as human experience and judgment are increasingly replaced by machine-generated knowledge that receives excessive amounts of trust.

Another overarching issue related to DNA databases is that although legal texts and technical protocols often speak of DNA samples that are given voluntarily, the voluntary aspect of such an act is dubious in light of the consequences of refusing to volunteer a sample in most cases. Volunteers fall mostly into one of two groups. The first group comprises people who are potential suspects, for the purpose of comparing their DNA with traces from the crime scene. The second group includes those who may have left their DNA at a crime scene for legitimate reasons (friends, employees, etc.). Such individuals are often requested to volunteer DNA samples to eliminate their DNA profiles from the crime-scene stains. If individuals in the first group refuse to provide samples, they typically attract suspicion, the assumption being that if people have nothing to fear, they have nothing to hide and that, in turn, refusing to volunteer a sample is a *de facto* admission of guilt. This is a very problematic conclusion, of course, because there may be many good reasons for people wanting to protect their privacy other than the need to hide criminal deeds (much like people who draw curtains). In certain jurisdictions and contexts, people refusing to volunteer samples even render themselves official suspects. If people in the second group refuse to provide samples, they either attract suspicion as well – for example, a neighbor who was not among the suspects could suddenly become one – or it would be explained to them that providing samples is in their best interests. In both cases, although informed consent forms would normally be signed, it remains questionable how voluntary such consents can be considered to be.

With the increased ability to extract DNA from even minuscule biological samples, many law-enforcement agencies have turned to abandoned DNA samples when suspects refuse to comply with requests for samples. In this procedure, police can retrieve DNA from saliva left on cigarette butts, glasses, cans and bottles, pizza crusts, or even spit on the sidewalk. American law generally allows such uses of biological material because obtaining them requires neither access to the body nor a search warrant (because the sample is taken from a public, rather than a private, space (Winickoff, 2004; Genetics and Public Policy Center, 2008)).

Finally, with the technological tools advancing fast, the scenario of using the full sequence of a person's genome, rather than a selected set of genetic markers, for identification purposes may soon be technically and financially feasible. Despite the significant costs that changing DNA databases from STR profiles to whole-genome information would incur, it is unclear for how much longer forensic genetic databases will stick to the present format. Many critics are concerned about governmental authorities' holding whole-genome information of individuals because of the comparative wealth of information regarding disease predispositions and traits that can be obtained from a full sequence in contrast to an STR profile. It should be noted, however, that whole-genome sequences do not predict the health or other phenotypic traits of a person entirely, with few exceptions. One of the major lessons from the Human Genome Project so far has been that genetic information alone typically tells us very little. Moreover, it is possible that once people's genome sequences are routinely held in the clinical domain, or even on a person's own computer, it is possible that genomic information will be seen as less sensitive than is the case today.

This article is reproduced from the previous edition, volume 9, pp. 5740–5745, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

A number of definitions of forensic psychiatry are considered, looking at the development of the concept and its practice in the USA, Canada, Britain, and Europe. The relationship between criminal law, civil law, and forensic psychiatry is traced. The author also considers the legal regulation of psychiatry, the special clinical skills needed (particularly in evaluating and treating violent patients), and the likely future organization and direction of the field.

A number of definitions of forensic psychiatry must be considered. The American Academy of Psychiatry and the Law (AAPL) (1985) endorses the definition of forensic psychiatry adopted by the American Board of Forensic Psychiatry Incorporated which is:

> Forensic Psychiatry is a subspecialty of psychiatry in which scientific and clinical expertise is applied to legal issues in legal contexts embracing civil, criminal, correctional or legislative matters: forensic psychiatry should be practiced in accordance with the guidelines and ethical principles enunciated by the profession of psychiatry.

In the preface to the British textbook of forensic psychiatry, its field of operation is defined as

> the overlap, interface, and interaction of psychiatry and the law in all its aspects; criminal behaviour, civil litigation, family law, the diagnosis, care and treatment of psychiatric patients where the disorder is associated with abnormalities of behaviour, legislation and numerous other problems such as the management of violence in the study of sexual deviation.

It adds that

> forensic psychiatry continues to be concerned primarily with mentally disordered offenders, but now encompasses a wide range of offences and gives much more prominence to diagnosis, management and treatment in prison, hospital or the community using the skills of psychologists, nurses, social workers, and probation officers in addition to psychiatrists.

The Canadian approach to forensic psychiatry mirrors the British definition as is seen in the recent application for subspecialty status by forensic psychiatry under the auspices of the Canadian Academy of Psychiatry and the Law. The goal of forensic psychiatry is defined as

> promoting the mental health of Canadians involved in legal matters. We aim to provide a functional interface between psychiatry and the law and to improve Canadian society as a whole through early intervention programs, better diagnosis and treatment and ultimately a reduction in offending.

In twentieth-century Europe, forensic psychiatry has generally centered on advances in the fields of neurology, psychiatry, and sciences related to these disciplines. In general terms, although there is no single definition of forensic psychiatry in Europe, it would tend to follow the British and Canadian approaches. In summary therefore, as we move into the twenty-first century there appears to be a convergence of the American definition of forensic psychiatry with the British, Canadian, and European definitions which relate to the evaluation and treatment of the mentally abnormal offender while at the same time being involved in the psychiatric assessment (for legal purposes) of fitness to stand trial, criminal responsibility in forensic psychiatry dealing with criminal matters, and similar assessments involving the civil aspects of the law. As we approach the twenty-first century, forensic psychiatry in all parts of the world appears to be moving and establishing its roots as a medical specialty and a subspecialty of psychiatry. Even though the medical roots are emphasized, it is quite clear that the forensic psychiatrists must be familiar with basic issues in law.

The Concept

The forensic psychiatrist needs to be an expert clinician as well as being well versed in law and psychiatry as it applies in the jurisdiction where he or she lives. Law is understood to encompass criminal, civil, and mental health law. In medicine as well as the social sciences there is an increasing number of attempts to complete research studies involving large samples in order better to define the characteristics of disease and aberrant as well as normal behavior. This has led to progress in many areas including forensic psychiatry. This allows the individual to be classified according to whether they have certain clinical and other characteristics in common with a certain reference group. An estimate of the individual's personality characteristics can be measured against a reference sample. The difficulty in forensic psychiatry is that the legal system looks at unique characteristics of a given individual before the courts, rather than any theoretical concept of how he or she may fit a given reference group. This can potentially create a conflict where the scientific aspect of forensic psychiatry could be seen as more prejudicial than probative in the context of the legal system.

The development of forensic psychiatry in Britain, Europe, and the United States was based on historical events in the eighteenth and nineteenth centuries. In Britain the writings of Sir Mathew Hale and the trials of Arnold, Ferris, Hadfield, Oxford, and McNaughton were major landmarks in the recognition of forensic psychiatry. The development of the Bethlem Hospital and later Broadmoor as special facilities for the criminally insane were also fundamental to the growth and development of forensic psychiatry. This was extended to other facilities such as the special psychiatric facilities at Rampton and Parkhurst in the early part of the twentieth century.

The development of forensic psychiatry in Europe followed a similar path. Forensic psychiatry emerged from events in the eighteenth and nineteenth centuries. The French Revolution brought to light documents about prisons, workhouses, and civil hospitals being used to detain members of the public. This was directed specifically to the way and rationale for the detention of persons who had been found insane. Concerns over the method of detention led to pressure for scientists of the day to define insanity more precisely. The influence of religion declined and this allowed the scientific roots of modern clinical psychiatry to develop. Philippe Pinel had an enormous influence in his *Medico-Philosophical Treatise on Mental Alienation or Mania*, which was rapidly translated into English and German. This led to a system of classifying mental disorders that was soon adopted in Europe and England. This helped in the development of forensic psychiatry as it brought more consistency to the testimony in insanity hearings before the courts. Esquirol, Morel, Lombroso, Krafft-Ebing, and others contributed to these important advances. As in Britain, special institutions for the criminally insane were developed and further research occurred in these institutions.

The United States saw a similar development with Benjamin Rush delivering the first lecture on forensic psychiatry under the guise of medical jurisprudence. The lecture covered topics ranging from civil incompetence caused by psychiatric disorder, and financial incompetence, to mental disorder and criminal responsibility. Rush was followed by Beck who in 1823 published *Elements of Medical Jurisprudence*. He referred to British and French psychiatry as well as Benjamin Rush in his book. Isaac Ray followed Rush and Beck and published the *A Treatise on the Medical Jurisprudence of Insanity* in 1838. This was used to defend Daniel McNaughton. Ray's approach in which he carefully studied the law and the judicial opinions of the day – in particular, anything in the law that obstructed the psychiatrically ill (the insane) being able to receive treatment. He became the superintendent of the Maine Insane Asylum and later the Butler Hospital. Perhaps most importantly he was one of the original founders of the American Psychiatric Association, and was its President from 1855 to 1859. In 1869 Ray went on to write a paper *Confinement of the Insane* that has remained fundamental to forensic psychiatry throughout the twentieth century.

> In the first place, the law should put no hindrance in the way of the prompt use of those instrumentalities which are regarded as the most effectual in promoting the comfort and restoration of the patient. Secondly, it should spare all unnecessary exposure of private troubles and all unnecessary conflict with popular prejudices. Thirdly, it should protect individuals from wrongful imprisonment. It would be objection enough to any legal provision, that it failed to secure these objects, in the completest manner.
>
> (Ray, 1869).

Highly significantly, Quen writing in *The Principles and Practices of Forensic Psychiatry* (1990) reports 'These elements remain necessary, valid, and unachieved in America today.'

As outlined above forensic psychiatry was fundamental to the development of psychiatry in the eighteenth and nineteenth centuries and was adopted by the founders of British, European, and American psychiatry as part of their role to promote psychiatry as a medical specialty.

Criminal Law and Forensic Psychiatry

This involves fitness-to-stand-trial evaluations and assessments for criminal responsibility. It involves the forensic psychiatric assessment of mentally abnormal offenders. The forensic psychiatrist is, by virtue of his or her professional training, an expert in psychiatry and specifically in mentally abnormal offenders. This expertise is applied to legal matters such as fitness to stand trial and criminal responsibility. The challenge to the forensic psychiatrist is that the traditional doctor–patient relationship does not exist under these circumstances. The traditional aims of psychiatry of treating or helping the patient are also not obvious and may even be contradicted. The definition of forensic psychiatry by the well-known American forensic psychiatrist Dr Seymour Pollack (1974) addresses these contradictions. Pollack defined forensic psychiatry thus:

> forensic psychiatry is limited to the application of psychiatry to evaluations for legal purposes. Psychiatric evaluation of the patient is directed primarily to the legal issues in which he is involved, and consultation is concerned primarily with the ends of the legal system, rather than the therapeutic objectives of the medical system.

Pollack is correct in terms of evaluations for fitness to stand trial and criminal responsibility. In the former, the initial role of psychiatric evaluation is to establish the diagnosis, from the standpoint of either a medical illness or a psychiatric disorder affecting the person's mental functioning. Once this has been established the next task for the forensic psychiatrist is to assess whether the degree of disorder present affects the person's capacity to proceed to trial. The legal basis may vary slightly between jurisdictions but all are similar and would be analogous to Section 2 of the Criminal Code of Canada, which defines 'unfit to stand trial' as follows:

> unfit to stand trial means unable on account of mental disorder to conduct a defence at any stage of the proceedings before a verdict is rendered or to instruct counsel to do so, and, in particular, unable on account of mental disorder to

a. understand the nature and object of the proceedings
b. understand the possible consequences of the proceedings, or
c. communicate with counsel (*Section 2 Criminal Code of Canada 2000*).

The process is clearly conducted for a legal purpose and, arguably, not necessarily in the person's best interest, as it may mean finding them fit for trial which may in turn result in a guilty verdict and possibly lengthy incarceration in a correctional setting. Alternatively, if they were found unfit and remained unfit, while they would still be incarcerated, they would probably be detained in a hospital setting. In Canada and most other jurisdictions, a finding of unfitness means that a judicial hearing would follow as to whether psychiatric treatment would render the individual fit to stand trial. In Canada this could result in a treatment order issued by a judge, ordering psychiatric treatment (most commonly antipsychotic medication) to render the person fit to stand trial. This can be done independently of the person's capacity to consent or refuse psychiatric treatment.

An assessment of criminal responsibility involves judging whether the person's mental status at the time the crime took place rendered him or her incapable of appreciating the nature of their actions as well as knowing whether their actions were wrong. It is beyond the scope of this article to go into criminal responsibility in detail as the legal basis varies considerably in different jurisdictions. This particularly true in the United States where the criminal law is under state jurisdiction and therefore each state varies in terms of what it uses as the legal basis for a finding of not criminally responsible on the basis of mental disorder. The most commonly used standard in Western countries is the McNaughton Test or some modification of the test. In recent years a number of American states have either abolished or severely limited the application of 'insanity' (mental disorder) to reduce the *mens rea* component of criminal responsibility. In order to be criminally responsible for a crime the state must prove the accused committed the unlawful act (*actus reus*) and that they also had the intent to commit the crime (*mens rea*). Mental disorder if present at the time the crime was committed can negate *mens rea*, leading to a finding of 'not guilty by reason of insanity,' not criminally responsible on the basis of mental disorder, or guilty but mentally ill. Such a verdict usually results in confinement in a forensic psychiatric facility until the acquitee is regarded as having recovered and no longer being dangerous to the community at large. In other cases, a mental disorder may result in a diminishing of criminal responsibility, allowing the accused to be found guilty of a lesser offence carrying a less severe penalty. This is seen in situations where a homicide has been committed and the individual suffered from a mental disorder at the time of the homicide. The degree of mental disorder is regarded as not sufficient to negate *mens rea* but to reduce it. This could result in a finding of manslaughter as opposed to murder where the intent to kill was reduced although the accused was still criminally responsible for the death of the victim. The original McNaughton Test was strictly a cognitive test. In its original form it was: *To*

establish a defence on the grounds of insanity, it must be clearly proved that at the time of committing the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or if he did know it, that he did not know he was doing what was wrong.
(Quoted in Hunter and MacAlpine, 1963.)

Various modifications of the original McNaughton Test have occurred in the United States and elsewhere. The most important of these has been the adoption, in the United States, of the American Law Institute Test (ALI Test), which includes both cognitive and volitional aspects. To complicate things even further the actual legal interpretation of the meanings of the various tests of criminal responsibility is subject to case law. This means the interpretation may change, depending on a specific interpretation by a particular judge in a specific court case that is upheld by various appeal courts. Forensic psychiatrists who act as expert witnesses in cases of criminal responsibility based on mental disorder are therefore becoming involved in a very complicated process where they have to use their psychiatric skills initially to establish a psychiatric or medical diagnosis. Drawing on the observations of others as well as the medical history of the accused, they must establish, by a process of reconstruction, whether the disorder was present at the time of the offence. If it was present, they must assess its degree or severity and how that would affect the operating mind of the accused both cognitively and possibly volitionally. Then they must form an opinion with reference to the legal test for criminal responsibility in the particular jurisdiction where the trial is being held. He or she will need a working knowledge of the case law interpretations as they apply in the specific jurisdiction and in the specific case. Finally, as expert witness he or she must understand the facts of the case as they emerge at the time of the trial and be able to incorporate them into the opinion being rendered.

In addition to criminal responsibility and fitness to proceed with trial, forensic psychiatrists are also involved in the sentencing of mentally abnormal offenders. Here the role of an expert is to address the third principle of sentencing, which is rehabilitation (the first two being retribution and deterrence). In certain jurisdictions this may be the most prominent role for the forensic psychiatrist as it is used to mitigate the sentence while at the same time allowing the judge to direct treatment in a correctional facility for a psychiatric disorder. It therefore provides a link between forensic psychiatry and correctional psychiatry. This linkage varies in different jurisdictions and countries according the degree of development of forensic psychiatry and the availability of treatment resources in the correctional system. A highly contentious issue related to sentencing is the participation of forensic psychiatrists in the death penalty process in the United States, including pretrial assessment, the sentencing phase, the determination of competence to be executed, and most controversially the assessment of restoration of competence to be executed as a result of psychiatric treatment. Most psychiatrists but perhaps more forensic psychiatrists have to give expert evidence in court (Rix, 2011).

Civil Law and Forensic Psychiatry

This branch of forensic psychiatry involves psychiatric malpractice; psychiatric disability determinations; personal injury evaluations; testamentary capacity and guardianship;

and family law matters, including parental competence and child custody evaluations. Included here is the specialty of the child and adolescent forensic psychiatrist. These individuals must combine the skills of two psychiatric subspecialties, namely, child and adolescent psychiatry, and forensic psychiatry. In some university divisions of forensic psychiatry these skills are available through a family court clinic. This clinic would receive consultations from the family court system to evaluate parental competence in child abuse and neglect cases and also assist in determining the best interests of the child in divorce custody cases. Family court clinics have also traditionally provided evaluation of young offenders. The evaluation of young offenders, principally adolescents, requires the clinical skills and experience necessary for evaluating children and adolescents. The importance of these dual skills cannot be underestimated and at times has called for the recognition of a sub-subspecialty of child and adolescent forensic psychiatry in some countries.

Testamentary capacity may be a relatively small component of forensic psychiatry, but there is no doubt as to its complexity and the special skills necessary for these retrospective evaluations and being able to communicate the evaluation to the legal authorities.

The Legal Regulation of Psychiatry and the Forensic Psychiatrist

The legal regulation of psychiatry involves informed consent and competence; the right to refuse psychiatric treatment and the right to psychiatric treatment; psychiatric hospitalization and involuntary civil commitment; outpatient civil commitment; confidentiality; the duty to warn or protect against professional misconduct, including the impaired physician, competence to practice, and professional sexual misconduct. These are areas of psychiatry and the law where the average psychiatrist also needs to develop skills and competence and are, therefore, not an exclusive area of practice for the forensic psychiatrist. The forensic psychiatrist, however, contributes special skills and training in the legal system, and the skill to be a competent expert witness. This means their role is to assist the non-forensic psychiatrist by consultation and advice and, in the more complex cases, forensic psychiatric expertise may be desirable.

Special Clinical Skills of the Forensic Psychiatrist

A wide range of special clinical skills is unique to the forensic psychiatrist. Special skills in evaluating and treating violent psychiatric patients are a fundamental requirement for all forensic psychiatrists. This is also expanded to include the assessment of the danger posed by an offender and risk assessment, as well as the risk management of violent mentally abnormal offenders. Associated with these clinical skills are skills in assessing antisocial personality disorder as well as impulse control disorders. Because of the association between organic brain dysfunction and impulsivity and violence, forensic psychiatrists need to develop skills in assessing the neuropsychiatric aspects of psychiatric conditions that can result in violence or can affect competence. They also need to be able to evaluate and treat the most severe and violent major mental disorders. Forensic psychiatrists must develop special skills in evaluating malingering and the use of hypnosis. The forensic psychiatric aspects of certain psychiatric disorders (e.g., multiple personality disorder) are also within the skill set of the average forensic psychiatrist. The assessment and treatment of sexual deviation is also a required skill. In addition assessing capacity to consent becomes important (Zimond, 2013) although all psychiatrists are expected to do this.

Correctional Psychiatry

The strict definition of correctional psychiatry is 'psychiatry practiced within a correctional system.' Broader definitions would include any agency of social control that is involved in the treatment and rehabilitation of adult or juvenile offenders. These populations have significant psychiatric morbidity and clearly would benefit from psychiatric intervention and this had led to a growth of correctional psychiatry in the last few decades. There is a close relationship between correctional psychiatrists and forensic psychiatrists with correctional psychiatric programs often being outreach programs of university departments of forensic psychiatry (as, for example, in Canada).

Organization and Future of Forensic Psychiatry

This is a subject of debate in North America at the beginning of the twenty-first century. There is a consensus that the future growth and development of forensic psychiatry must lie within the field of medicine as a subspecialty of psychiatry. This is already well established in general terms in Canada and Europe. If we accept this consensus, some comment as to the ideal forensic program is warranted. This author strongly endorses the subspecialty status of forensic psychiatry as a critical component of its future development. This implies that the ideal forensic program would be an academic division within a university department of psychiatry. In turn, this would mean that education, clinical training, and research would be fundamental components of the program. General psychiatric residents should be required to do a rotation as part of their residency requirement. As the largest interface between medicine and the law is between psychiatry and the law, it should be part of the basic training of all psychiatric residents. It is almost impossible for the average psychiatrist to go through his career without some interaction with law and psychiatry tribunals, the criminal justice system, or the civil legal system.

An ideal program would provide fellowship training in forensic psychiatry in an accredited program for a minimum of one year. The forensic clinical program should have a medium or maximum inpatient assessment unit to provide pretrial evaluations of fitness and criminal responsibility. In addition, inpatient and outpatient facilities are required for the treatment and rehabilitation of individuals who have been found unfit to stand trial or not criminally responsible on the basis of mental disorder. The length of stay should allow for both acute and chronic care so a cautious approach to treatment and

rehabilitation would prevail. There also need to be outreach programs to correctional facilities and an active participation in pretrial diversion programs. In an ideal situation, specialized clinics for the assessment and treatment of sexual deviation, and aggression and impulse control disorders should also be present. A family court clinic with child and adolescent forensic psychiatrists on the staff should also be included. A multidisciplinary team approach to assessment and treatment is essential. Research into all aspects of forensic psychiatry is critical for its future growth and the development of its profile as a medical subspecialty.

Abstract

Forensic psychology is the branch of psychology concerned with the production and application of psychological knowledge and principles within the legal process. Although forensic psychology is a relatively young discipline, psychology and law have been intertwined since the dawn of recorded history. Today there is hardly an area of the law where psychological expert testimony is not being implemented and there can be no doubt that forensic psychology has made significant contributions to the execution of justice. Consequently, the forensic psychologist often serves as an expert witness in court. The activities of forensic psychologists include the assessment of competency to stand trial and criminal responsibility, determining the validity of defenses (such as intoxication, amnesia, dissociative identity disorder, and post-traumatic stress disorder), predicting violent behavior, assessing eyewitness testimony and personal injury, providing testimony on appropriate sentencing, profiling, and contributing to child custody evaluations. The most important forensic assessment procedures are the forensic interview and psychological testing, while forensic hypnosis is also sometimes used. Because reliability is questioned, the polygraph is seldom employed. The status of forensic psychology can be increased by quality research, presenting objective and critical evidence, and realizing that there are areas in which the contribution of forensic psychologists is questionable.

Forensic psychology is the branch of psychology concerned with the production and application of psychological knowledge and principles within the legal process. (The term 'forensic,' meaning 'legal' or 'judicial,' is derived from the Latin word *forensis*, which literally means 'relating to the forum or market.' In ancient Rome, a forum was an open square, which served as a market, as well as a place where legal matters were disposed of.)

Historical Background

Since both psychology and law are concerned with human behavior, they have been intertwined since the dawn of recorded history (Gudjonsson and Haward, 1998). Indications of interest shown in the law by philosophers, from whose ranks psychology would later develop, are found in the earliest Asian, Egyptian, Greek, and Latin writings. Later Greek philosophers continued to express themselves on practical questions of law and topics that today constitute the subject matter of psychology. For example, Plato (ca. 427–347 BC) in his *Republic* considered the question whether mentally disordered people were responsible for their behavior (Allan, 1995). However, it took more than 2000 years for psychological knowledge to mature to a level where it was officially allowed in the courtroom for the first time. This happened in 1896 when Albert Von Schrenk-Notzing, student of Wilhelm Wundt who founded the first psychology laboratory in Germany in 1879, testified in a murder trial concerning the effect of pretrial publicity on memory and suggestibility (Blau, 1998). Since then, forensic psychology has made great strides. As we enter the twenty-first century, there is hardly an area of the law where psychological expert testimony is not implemented. Ewing (1985) believes that the modern justice system could not function without significant participation by behavioral scientists such as psychologists.

Roles of the Forensic Psychologist

As both psychology and law essentially cover all aspects of human behavior, it is understandable that the forensic psychologist serves as an expert on a variety of matters including those considered in the following sections.

Competency to Stand Trial

Also known as fitness to plead, competency to stand trial refers to the defendant's mental capacity to make a proper defense, i.e., to understand the legal proceedings and the charges against him or her.

Contrary to popular opinion, the mere existence of a mental disorder *per se* does not render an individual incompetent to stand trial. Many mental disorders are of such a nature and intensity that the defendant's competency is not significantly influenced. The crucial question is whether the mental disorder affects the defendant's current functional abilities within the context of relevant legal criteria for determining competency (Gudjonsson and Haward, 1998).

As laws and 'legal cultures' differ from country to country, it is understandable that statistics concerning competence to stand trial will vary considerably. For example, proportionally speaking, about 100 times more defendants in the USA are found incompetent than in England and Wales. Even within one country, the percentage of defendants found to be incompetent often varies between 1% and 80% across jurisdictions.

It does seem that individuals adjudicated incompetent to stand trial often have certain characteristics in common, such as

a history of mental health treatment (especially for schizophrenia and depression), lower intellectual functioning, and a present charge of violent crime.

The evaluation of competency is usually very reliable and the agreement rate between psychologists often exceeds 80%. Next to the traditional assessment techniques, particularly the clinical interview, several competency assessment instruments are also used.

Criminal Responsibility

Criminal responsibility (liability/accountability) should not be confused with competency to stand trial. Competency to stand trial is specifically concerned with the defendant's mental capacity during the legal proceedings. Criminal responsibility, also known as the insanity defense, refers to the time of the alleged offense and more specifically asks the question whether the defendant had the mental capacity to distinguish between right and wrong at the time of the alleged offense and could control his or her conduct accordingly. Should the defendant be found not criminally responsible, he or she rarely goes free. The person is usually referred to a mental health facility where he or she will remain as long as the commitment criteria are met.

The insanity defense is one of the most controversial issues in criminal law. One reason for this are the many misconceptions surrounding this plea. For example, although the public believes (probably as a result of the publicity given to such cases) that the insanity plea is very often entered, such cases are rare: often fewer than 1 in every 1,000 criminal cases. The success rate of the defense varies from country to country and from jurisdiction to jurisdiction, with 25–50% as a broad average.

Most defendants whose insanity pleas are successful are diagnosed with major psychotic disorders and have extensive mental health histories, often accompanied by prior civil commitments or findings of incompetence (Golding et al., 1999).

Insanity evaluations are usually regarded as more complex than competency evaluations. It is, after all, exceedingly difficult to determine what another person was thinking, feeling, and doing at the time of an offense that usually happened weeks, months, or even years earlier (Bartol and Bartol, 1994). However, it seems that specialized training and experience can lead to an agreement rate between mental health professionals of more than 80%. Several measuring instruments have been developed to assist mental health professionals in their assessment of the insanity plea.

Other Defenses

Next to competency to stand trial and criminal responsibility, the expertise of psychologists is employed in several other defenses in both criminal and civil cases.

a. *Intoxication* by alcohol or other drugs, because it is self-induced and temporary, is seldom given complete exculpatory effect (Melton et al., 1997). The major exception is when the substance abuse has been prolonged to a point where it has produced a serious mental disorder. However, in most countries voluntary intoxication can be used as a diminished capacity defense claim. In such cases mental health professionals have to produce evidence that the intoxication did indeed affect the defendant's mental capacity significantly.
b. *Amnesia* (the total or partial loss of memory) at the time of the offense is one of the most common defenses heard in the criminal court, especially concerning violent crimes (*see* Amnesia: General). It is also one of the most difficult defenses to assess. It is not only difficult to determine the weight that should be given to the claimed amnesia, but also to distinguish between genuine and simulated amnesia. An even more complex task is to determine whether the defendant was really amnesic when committing the crime, or whether he or she only developed the amnesia afterwards. Although psychologists frequently give expert testimony on amnesia, their ability to assist the court with scientific evidence is questioned. Courts are therefore often skeptical about accepting their testimony as a viable defense element.
c. *Dissociative identity disorder*, formerly called *multiple personality disorder*, is primarily characterized by the presence of two or more distinct personalities that in turn take control of the person's behavior (American Psychiatric Association, 1994). However, the disorder is highly controversial and sometimes called the 'UFO of mental health.' Many mental health professionals believe that the disorder does not exist and amounts to no more than role playing. Although screening instruments and structural interviews have been developed and hypnosis is used to diagnose dissociative identity disorder, experts admit that it is very difficult to distinguish between real cases and malingering (Alloy et al., 1999). It is therefore understandable that legal professionals tend to be very cautious about making use of this defense. However, in rare cases in several countries, dissociative identity disorder has been accepted as a defense, ranging from an insanity plea to extenuating circumstances.
d. *Post-traumatic stress disorder* (PTSD) is characterized by intensely distressing symptoms (e.g., irritability and sleeplessness) caused by exposure to a traumatic event such as rape, death, combat, accident, and even harassment and difficult work conditions (*see* Post-Traumatic Stress Disorder). PTSD can therefore be a factor in both criminal and civil cases. However, establishing the existence of PTSD poses several difficulties for the forensic psychologist. For example, the validity of the diagnoses is often questioned. Although psychological measuring instruments and techniques to assess PTSD are available, they are usually based on self-report. The result is that malingering cannot be ruled out easily.

Prediction of Violent Behavior

As one of the primary duties of the court is to protect society, assessing the offender's potential for future violence often forms an integral part of the judicial process. This is especially true if the offender is charged with a violent crime. Determining the propensity for future violence is therefore an important part of the forensic psychologist's functions.

However, the role of the mental health professional in violence prediction is controversial. The main reason for this is that past research showed that mental health professionals have a bad track record when it comes to predicting the probability of a person committing future violence, and even more so when it comes to predicting the type and severity of such potential violence. As such, professionals can pay a heavy social, professional, and legal price for failing to predict violent behavior, they tend to 'play it safe' and therefore often overpredict. The result is that research has shown that more than 50% of persons predicted likely to commit future violence, do not do so.

Ongoing research in this field is fortunately beginning to bear fruit. For example, several variables have been identified which can be regarded as risk factors for violence, e.g., a history of violence, substance abuse, symptoms of a psychosis or antisocial personality disorder (psychopathy), weapon availability, early onset of violent behavior, and absence of social support. Measuring instruments to assist psychologists have also been developed.

Eyewitness Testimony

'It is … inevitable that what a witness says in court will be a subjective and incomplete version of 'the truth' interspersed with small portions of fiction.' Although most psychologists will agree with this statement by Ainsworth (1998, p. 3), the testimony of an eyewitness still remains a very important part of evidence presented in both criminal and civil cases. However, as a result of a rapidly growing data bank in this widely researched area, especially in the 1980s and 1990s, the courts are currently examining some of their assumptions about the reliability and thus the value of eyewitness testimony. It is therefore understandable that courts increasingly rely on psychologists to provide expert testimony in this regard.

The following are some of the more important research findings that have been used in court by psychologists: (a) eyewitnesses tend to be less accurate in stressful situations; (b) people experience difficulty making cross-racial identifications; (c) eyewitnesses focus on weapons rather than faces; (d) memory decay starts immediately after a perception; (e) memory gaps are often and easily replaced by unconscious fabrication or by external suggestions; (f) there is not necessarily a correlation between the degree of certainty evinced by the eyewitness and accuracy (Melton et al., 1997); and (g) although younger children are often more suggestible and remember less detail than older children and adults, they do not necessarily have poorer memories (Saywitz and Goodman, 1996).

Personal Injury

The world is progressively becoming a litigious society in which monetary compensation is sought for almost any maloccurrence (Tsushima and Anderson, 1996). As many such claims involve 'psychological pain and suffering,' psychologists are increasingly becoming involved in so-called mental injury cases. Although determining the presence and cause of mental injury constitutes the bulk of psychologists' work in this field, they are also involved in injury claims of a more physical nature, e.g., to assess brain damage or determine the psychological effect of losing a limb.

To assess whether the plaintiff does indeed suffer from a mental injury is not always easy. First, it has to be proved that there is a causal relationship between the specific incident and the plaintiffs symptoms, i.e., that the symptoms did not already exist before the incident or were not caused by other factors after the accident. Second, as possible financial remuneration is involved, plaintiffs often tend to exaggerate or even fake their symptoms. No foolproof method to determine such relationships and distinctions is available. However, by using the most objective, valid, and reliable tests appropriate to the complaints, conducting thorough interviews, and carefully recording case notes and test reports, psychologists can make a valuable contribution towards clarifying the extent to which psychological factors may be involved in personal injury cases (Butcher and Miller, 1999).

Sentencing

If a defendant is found guilty of the charge against him or her, the court has to impose an appropriate punishment. In most countries the aim of such punishment consists of a combination or all of the following: deterrence, retribution, prevention, and rehabilitation. Since these goals have a strong psychological element and psychologists are supposed to be well equipped to provide the court with a psychological profile of the defendant, they often testify in this regard. For example, the psychologist can provide the court with information concerning the defendant's potential for future violence, the sincerity of the repentance shown, the possibility of rehabilitation, a variety of mitigating factors, and the effect of different sentences on the defendant as a unique individual.

Although there seems to be a high correlation between psychologists' recommendations and the final sentencing decision of the courts, it remains an open question as to what extent the courts do indeed take the testimony of the psychologist into account or merely use it to 'scientifically' justify decisions they have already made (Melton et al., 1997).

Profiling

Criminal profiling refers to the process in which the nature of a crime is used to make inferences about the personality and other characteristics of the likely offender.

The sensational and dramatic elements of profiling portrayed in various well-known movies, television series, and books (usually those depicting a serial killer) seem to be in sharp contrast with reality. Profiling is not widely accepted in the psychological and legal community, and some courts have even ruled profiling testimony inadmissible. There are two main reasons for this (Gudjonsson and Haward, 1998). First, a criminal profile only gives a broad indication of the type of person who may have committed the crime. It does not indicate a specific individual who happens to fit the profile. The profiler is therefore unable to say whether it is more probable than not that a specific offender did, in fact, commit the crime. Second, there is no scientific evidence to support the reliability and validity of criminal profiling in solving crimes. Indeed, it

seems that when profiling does assist the police in solving a case or in opening up new lines of inquiry, it is the exception rather than the rule.

On the other hand, it cannot be denied that criminal profiling has proven helpful in some, albeit exceptional, cases. However, much more research needs to be done before criminal profiling will earn its place as a valuable forensic tool.

A variation of profiling that has evoked some interest in the news media is psychological autopsy, which comprises the compilation of a psychological profile of especially well-known deceased individuals. It is also used in suicide cases, for example, to determine whether the deceased could indeed have committed suicide. However, as in the case of criminal profiling, its reliability and validity are also questioned.

Child Custody

With the worldwide increase in divorce rates and the resulting child custody battles between divorcing parents, mental health professionals have come to play an increasingly important role in such disputes.

Two principles play a major role in courts' decisions in child custody cases: the tender-years principle and the best-interest-of-the-child principle. The tender-years principle reflects the traditional belief that the mother is inherently better equipped to care for children of a 'tender age' (which particularly refers to children around or under the age of seven). However, several factors have led to the questioning and even abolishment of this principle in some courts. For example, research has shown that fathers and mothers are equally capable of fulfilling the psychological and other needs of children in their 'tender years.' The principle is also seen as a violation of equal gender rights. Most courts base their decisions in child custody cases on the best-interest-of-the-child principle, which involves criteria such as (a) the love, affection, and other emotional ties between parent and child, as well as between the child and his or her siblings or any other significant person; (b) the ability of the parent to provide for the child's psychological, educational, cultural, and environmental development; (c) the ability of the parent to provide the basic physical needs of the child, e.g., food, clothing, and housing; (d) the mental and physical health and moral fitness of the parent; and (e) the child's preference as to his or her custodian. However, this principle has also come under fire from critics who, for example, claim that many of the criteria are vague, difficult to assess, and open to subjective interpretation.

Assessment in child custody disputes usually includes interviewing the parents and children, as well as any other third-party source that may provide valuable information, observation of the interaction between especially parents and child, and the use of traditional psychological and specialized tests. However, the interview is usually recommended as the best method. The reasons are the following. The observation technique is regarded as artificial and thus unreliable (the individuals know that they are being observed). The traditional psychological tests are often irrelevant (e.g., there is no correlation between good parenthood and IQ). The specialized tests are also not very reliable and valid. It is generally accepted that a psychologist, acting according to professional guidelines, can make a valuable and often decisive contribution in child custody cases.

Forensic Assessment

Forensic assessment refers to the procedures, methods, and techniques that psychologists use to gather information in order to assist the court in coming to a final decision. The nature of the assessment will depend on the theoretical orientation, training, experience, and preference of the psychologist, as well as the nature of the specific case. Usually a combination of procedures, methods, and techniques are used.

The forensic interview can be considered the central element of the assessment process. The interview can be structured (the questions being determined and systematized in advance), unstructured (the interview being allowed to develop spontaneously), or a combination of the two. The forensic interview is much more than just an 'ordinary' interview. It is a scientific method for gathering information and requires specialized training and experience. As mentioned, it is usually necessary to interview not only the specific individual, but also family members, friends, and other third-party sources. Such collateral information may be helpful not only in acquiring a broader picture, but also in determining the reliability of the information provided by the different sources.

In addition to this basic assessment method, several others are employed, and examples are given below.

Psychological Testing

Virtually all forensic psychologists incorporate psychological tests in their assessment armament. Psychological test results can be powerfully persuasive instruments because of society's long-standing high regard and respect for these measuring instruments (Tsushima and Anderson, 1996). Many courts also seem to expect that such tests will be used.

However, it has also become clear that psychological tests have not always conformed to the high qualities attributed to them. Not only are the reliability and validity of many of the tests used by psychologists generally disputed, but also they have not been developed specifically for forensic issues. The result is that their usefulness in forensic settings is questioned. Attempts to develop specialized forensic assessment instruments have also not yet been very successful, mainly owing to psychometric flaws. Another problem especially encountered in underdeveloped and developing countries is that tests are used on groups for which they have not been developed. An example is the worldwide use of various American tests developed for the US population on groups for which they were not standardized. Cultural differences cast doubt on the reliability of such results.

On the other hand, can there be little doubt that, in the hands of a well-trained and experienced examiner who is well aware of the pitfalls, psychological tests can be very valuable tools and can provide valuable information.

Forensic Hypnosis

There are few topics in psychology more shrouded in mystery and misconception than hypnosis. Mainly responsible for this is the sensational representation of this technique by the movie industry, news media, and stage hypnotists. Even in the

scientific world controversy surrounds the hypnosis phenomenon, with some regarding it as a valuable tool in many areas, while others do not believe in the existence of such a state, and mainly contribute it to suggestion and role-playing (*see* Hypnosis, Psychiatry of).

The primary use of forensic hypnosis centers on enhancing the memory of a witness, victim, or even defendant, especially with a view to helping him or her remember forgotten or vague details of a crime. Most research shows that, compared with people who have not been hypnotized, people under hypnosis tend to recall more detail about an event. They also usually feel confident that their recollections are correct. However, their stories contain a great deal of inaccurate information, even more so than in the case of nonhypnotized subjects. It is generally accepted that forensic hypnosis is seldom more efficient in improving memory than any other standard psychoforensic procedure. Courts therefore hesitate to accept testimony acquired through hypnosis. In some countries such testimony is even inadmissible. Others do allow it, but usually only if certain safeguards and guidelines are applied. It is therefore important than forensic psychologists meet these preconditions if they wish to employ this controversial forensic tool.

Polygraph

The polygraph, also called 'lie detector,' is an apparatus that measures physiological variables such as heart rate, blood pressure, and respiration rate. Polygraphers believe that when people are asked threatening questions to which they respond by lying, physiological changes will occur which will show up on the polygraph record. This makes the polygraph a potentially valuable forensic tool.

Unfortunately, the validity of the polygraph leaves much to be desired. Polygraph results seem to be wrong in at least 30% of all cases. This concerns innocent people who are wrongly accused, as well as guilty persons who plead innocence. For this reason, most courts do not admit evidence based on polygraph results, or admit it only if it adheres to certain stipulations (e.g., that all parties agree to the test before it is administered).

Ironically, it seems that one of the polygraph's biggest strengths lies in people's belief that it is reliable. It seems that about 30% of suspects confess after they have failed a polygraph test (Memon et al., 1998). However, it does not necessarily mean that these suspects had been lying. It could also be that innocent suspects tend to confess because, having failed the test, they see little possibility of convincing the court of their innocence thereafter. By confessing they hope to get a lighter sentence.

The Future

Only a few decades ago the relationship between psychology and law was compared to an unhappy marriage. In the twenty-first century, it is rather regarded as a 'normal' marriage with its ups and downs, but definitely not heading for a divorce. There can be no doubt that both professions find the interaction and collaboration enriching.

However, in order to make full use of this interdependent relationship, much more needs to be done. The key lies in research, aimed not only at developing new procedures, methods, and techniques, but also at determining weaknesses in the general professional approach of forensic psychologists. Forensic psychologists should especially try to move away from the 'hired guns' stigma attached to them. This can only be achieved by telling 'the truth and nothing but the truth.' This principle can be best served by presenting objective and critical both-sides-of-the-story evidence without subjectively favoring one party. The saying, 'It is not a question whether forensic psychology is good, but what it is good at,' should also serve as a principle guideline for acknowledging that there are areas where little or no contribution can made and sticking to those areas where it is clear that psychologists are held in high esteem by courts. With such an approach and quality research, there can be no doubt that forensic psychology will flourish in the future.

Editor's Note

Forensics has been a strong growth area in anthropology, psychology, finance, and many other fields since 2000, due largely (it seems) to the popularity of television shows such as CSI or Bones; and the literature in these fields has grown rapidly. For recent overview, treatments of forensic psychology specifically, see Adler and Gray (2010). An important emerging field, not mentioned in Louw's original entry, is forensic neuropsychology. On this, see Larrabee (2012). Forensic psychology probably finds more application in criminal law and criminal behavior than in any other field; indeed, the popular image of the forensic psychologist has him or her on the stand testifying to the fitness of accused to stand trial. On crime and forensic psychology, see Bartol and Bartol (2012). The leading journals in the field are the American Journal of Forensic Psychology, founded in 1983 and published quarterly; and the Taylor and Francis Journal of Forensic Psychology Practice, published five times per year.

Formal Methods of Cultural Analysis

John W Mohr and Craig Rawlings, University of California, Santa Barbara, Santa Barbara, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Our focus is on methods of cultural analysis, and specifically on those methods that are formal in the sense that they rely upon the purposeful gathering (or simulating) of cultural data and a systematic analysis that involves at least some mathematically based technique. The meaning of culture is more complex, as scholars have understood cultural phenomena in very different ways across the decades and across the disciplines. These different goals in cultural analysis give rise to different types or styles of formal methods of cultural analysis. We briefly review the history of these methods in the social sciences and conclude with a description of some of the main arenas within which formal methods of cultural analysis are being deployed and actively developed today.

What Is a Formal Method of Cultural Analysis?

We describe developments in the use of formal methods of cultural analysis in the social sciences, focusing on approaches that rely upon the gathering (or simulating) of data concerning matters of culture. By this classification, it is precisely the use (either ultimately or potentially) of formal measurement practices and the construction of a data set that can be analyzed according to logical, relational, or other quantitative methods that define an approach to cultural analysis as formal in the sense of the term used here. We begin our article by describing different types or styles of formal analysis of cultural data. We then review some of the history of how these methods have been used for analyzing culture in the social sciences. We conclude with a description of a few of the main arenas in which formal methods of cultural analysis are currently being developed and deployed by research scientists.

Our title indicates a focus on formal *method*s of cultural analysis suggesting a survey of techniques but a more accurate description would be to say that we focus here on alternative research *programs* for studying culture each of which includes a shared tradition, organized communities with hierarchal social structures, shared ways of scientific knowing linked with (articulated into) shared systems and styles of practice which implies immediately that these are also technological ways of knowing and technological ways of doing (see Bourdieu, 1990; Pinch, 1986). A focus on methods alone strikes us as less productive since methods are never really neutral. For one thing, there are many examples where the same styles of data collection (e.g., interviewing or surveying) or the same styles of analyzing data (network analysis, linear modeling, or Boolean algebras) have been deployed in the service of quite different types of research goals.

The meaning of culture is inherently difficult to pin down, as scholars have understood cultural phenomena in quite different ways across the decades and across the disciplines, a topic that we take up here as well. As a start, recall that Raymond Williams (1977) traced the origins of the concept of culture from its early roots referring to "the growth and tending of crops and animals, and by extension the growth and tending of human faculties" (p. 11) through a series of changes and developments. With the rise of Romanticism, Williams notes that culture takes on a new meaning as something set against the character of modern life "as distinct from or actually opposed to 'civilization' or 'society' in its new abstract and general sense … 'culture' as a general process of 'inner' development was extended to include a descriptive sense of the means and works of that development: that is, 'culture' as a general classification of 'the arts,' religion, and the institutions and practices of meanings and values" (p. 14–15). Williams identifies a second break in the concept of culture that he traces back to the original (eighteenth century) insights of Giambattista Vico and Johann Gottfried Herder on culture as styles of life, which then emerge full-blown in the nineteenth century associated with the idea that "a fundamental social process which shapes specific and distinct 'ways of life' is the effective origin of the comparative social sense of culture and its now necessary plural 'cultures'" (p. 17). While the theory of culture has changed, in some ways this age old split in thinking about culture still resonates today with how formal methods are applied to the study of culture today. On the one hand, a focus on culture as primarily concerned with domains of creativity and the arts, and on the other, those who would instead emphasize the study of culture as a 'way of life' founded perhaps on core patterns of understanding, believing, valuing, or moralizing. In this case, as Clifford Geertz offered a definition of culture as "an historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes toward life" (1973: p. 89).

For analytic purpose we distinguish between two types of formal research programs for studying culture. The first type, which we classify as interpretative or hermeneutic styles of cultural methods have as their goal advancing our ability to know or to understand a shared cultural meaning or form of collective understanding (or to simply assist in providing a reading of a cultural text). These are methods that are often grounded in views of culture that see systems of shared meaning (or core logics of understanding) as being what most deeply anchors an effective cultural analysis. Methods of content analysis are one example of a style of cultural research programs that are frequently associated with hermeneutic research goals. Hermeneutic style projects tend to focus on

speech activity (including texts) and their formalisms are generally geared toward helping the analyst to make sense of the speech data, system of discourse, or other forms of cultural expression. Here, cultural meanings can include larger types of shared cultural patterns (like ideologies, fields, and hierarchies of artistic tastes or institutional logics) (Friedland and Alford, 1991; Geertz, 1964; Swidler, 2003; Thornton et al., 2012; Wuthnow, 1989). But they might just as well be directed at smaller groups or organization level meaning systems, including those that Gary Fine calls idiocultures (Fine, 1979) or what Harrison White describes as netdoms – conjunctures of identities, networked together in a time and a place, with a foundation in shared collective meanings, ways of talking together and repertoires of stories. White says that this "presupposes the mixture of relation and topic, plus understanding" (White, 2008).

We classify other forms of measuring culture as non-hermeneutic. Here the goal is to measure aspects or traces of cultural forms, and then to use those measures as indicators (or factors) for understanding or explaining other social phenomena. One might also say that the goal of a non-hermeneutic program of cultural analysis is at least potentially a simpler approach to measurement since it comes without the added ambition of needing to also decipher the hermeneutic meaning of the cultural data that has been collected. DiMaggio sums it up, "Nothing is more central to the study of culture than the interpretation of meaning, yet nothing is more difficult" (DiMaggio, 2011: p. 294).

Some History

Early Uses of Data to Measure Culture

As states and state apparatuses grew, so too did their capacities and appetites for the gathering of systematic data on national, regional, and local populations (for taxation, conscription, tariff collection, and other administrative functions). They also developed measures of 'economic' indicators – the money supply, forms of wealth, the circulation and availability of commodities, etc. (Porter, 1986; Spengler, 1961) These endeavors were constitutive of the basic discursive, professional, and organizational cultures and informational infrastructures that facilitated the rise of modern states, political economies, and systems of surveillance. As this data was collected, so too were social scientists developing new mechanisms for measuring the types and characteristic qualities of the people who made up these nations (Foucault, 1970; Fourcade, 2010; Hacking, 1975, 1990; Lazarsfeld, 1961; Porter, 1986; Stigler, 1986). And as soon as these official statistics were being gathered, researchers began to make creative use of those measures to describe and analyze matters of culture.

In his classic review of the origins of quantification practices in sociology, Lazarsfeld (1961) recounts numerous efforts by pioneering social scientists to take the measure of norms, values, moral sentiments, and systems of shared meanings. Lazarsfeld (1961) dates the origins of modern demography to the work of Graunt in 1662. Spengler (1961) tells us that estimates of the supply of money were being made as early as 1694. State data efforts in this era were, however, spotty, unreliable, or altogether unavailable (in no small part because local populations were properly suspicious of state enumeration efforts). For many years, clever estimation strategies were relied on. As Lazarsfeld explains, "(T)he ingenuity of early scholars was directed mainly toward obtaining estimates of population size and age and sex distributions from meager and indirect evidence. Multiplying the number of chimneys by an assumed average family size or inferring the age structure of the population from registered information regarding age at the time of death were typical procedures in what was then called political arithmetic" (1961, pp. 149–150). But it was not only demography that was being estimated. The specialists in these arts, the political arithmeticians, prided themselves on showing the relationship between national populations (which were thought to express very specific characters), the nature of particular state administrations (which were often viewed in highly personalized terms), and the principles of good governance (which were a curious mix of theistic moralities and Aristotelian inspired protoscientific rationalities). In the process, topics regarding culture were mixed in with demographic facts, mercantilist tallies, and pseudosociological folk theories (often built around rhetorics of national historical dramas) (Lazarsfeld, 1961; Porter, 1986).

Elsewhere, Lazarsfeld sums up what he sees as the main trend in the early years of culture modeling by explaining that in the mid-nineteenth century, "Le Play assessed the religious feelings of the families he studied by examining their budgets and noting how much money they spent on candles for church masses. It was objected that church attendance might be a better indicator of the religious feelings Le Play sought to measure, and thus slowly the notion of time budgets – in addition to money budgets – developed. It was then further argued, that perhaps church attendance is indicative only of conformity to social customs; it is the attitude toward religion which really matters. And so attitude measures began their triumphant course" (Lazarsfeld, 1970: p. 65).

These early efforts at measuring culture have a distinctly Durkheimian flavor. The importance of culture is its role in the collective conscious – or the social glue that provides cohesion through shared beliefs and sentiments. Largely absent are the conscious deliberations over various interpretations of cultural objects, as well as more complex *systems* of meaning in which cultural processes unfold. Culture is subsumed by social structure, while the structures of cultural systems are not an empirical concern. It would take some time for culture to escape the confines of this larger functional edifice.

Kroeber's Analysis of Fashion Trends

An early example of a social scientist who sought to develop a precise set of formal measures of cultural forms was Alfred Kroeber (1919) who studied changes in women's dress fashions. Kroeber systematically coded a sample of images from a collection of women's fashion magazines (measured annually from 1844 to 1918). By taking basic measurements of the models and their gowns (the length of the figure, length of dress, width of dress at hem, width of dress at waist, etc.) and analyzing these data across time, Kroeber found some clearly visible and apparently cyclic trends in women's dress fashions. In one graph, for example, he shows the quick and unidirectional growth in the width of the skirt, neatly capturing the

fashion in crinoline hoop skirts out to an apex, followed by a steep decline (save for a short sartorial diversion by way of a widening of trains on the dresses). The data that are used for these analyses are very simple measures of size and ratio in women's evening fashions. This is cultural data but it is not hermeneutic data. In other words, whether meanings are ultimately at work in determining what goes on here or not, what was actually being recorded as data by Kroeber are just a simple set of measures assessing the geometric dimensions of the cultural forms (evening dresses), measures that turn out to be useful for illustrating increments of change in cultural forms over time. Kroeber's work is, in this sense, a classic and early demonstration of how nonhermeneutic measures of culture could be collected and usefully analyzed.

Stanley Lieberson (2000) finds a similar type of effect (80 years later) when he studies baby names. Lieberson calls this the ratchet effect. The cycle is explained by the idea that tastes involve establishing a distinctiveness, a difference from less-valued taste categories and that in a system such as women's fashion, part of what is valued is *the new* (as distinct from the old) and thus an important marker of the new is the length of the dress. If hem lines do not change, then the newness of the fashion is harder to perceive. So they must be different than last year's hem line. But if they go backward, to the length of the previous year, then again there will be a danger that the new will be confused with the old, with the really old – that is, with the *passé*. As a result the hem has to continue moving in the direction it has been moving in. And this continues until the hem hits an obstacle (the floor or some measure of moral propriety) at which point it has to reverse itself.

Lieberson (2000) shows that given names also exhibit the ratchet effect. Names turn out to be a good source for cultural data because they are collected very systematically (e.g., in birth records) and because they have increasingly become defined as free choices and thus they are subject to the vagaries of style. Names become appealing to a lot of people at the same time. As this happens, the name becomes more and more popular until such point that a given name will become too popular. As an explanation, Lieberson offers a basic thought experiment. Suppose you are about to name your child and you were searching for a name that appealed to you. And you hit upon a certain name. But you looked about you and you saw lots and lots of people with that name. So many people that you wanted your child to be different, to be special, to be given their own more unique name. And so you pick something else.

Lieberson describes both endogenous and exogenous effects. The former focuses on the means according to which taste moves. This depends on a largely tacit set of cultural affinity processes. Choices happen because within the sea of available names, some are in one's mind, others are not. Some sound nice to one's ear and others do not. Some seem like good things to choose and others do not. Culture in the end is about how the self is subjectively tuned into a complex, flowing field of cultural meaning systems. The choice of a child's name reflects how some social constellation of influences, embedded within an interlocking set of family, friend, and significant other networks, usually including a fantasized network of media personalities, are affected by the rise and fall of aesthetic appeals, and the ebb and flow of identity dilemmas and associations, all of which weigh down upon the moment when a child is announced to have a given name. Compare this with the theory of culture held by Kroeber. Like Durkheim, Kroeber was trying to demonstrate institutional effects, seeking to show that there are things that occur in cultural life that operate at a level, which is not just at the experience of a particular individual. But unlike Lieberson, he has little to turn to as a means of explanation. And, in the end, when he ponders about what might account for the regularities of culture he suggests, "The super-organic or superpsychic or super-individual that we call civilization appears to have an existence, an order, and a causality as objective and as determinable as those of the subpsychic or inorganic" (p. 263). In this sense, going beyond Durkheim, Kroeber creates a semiautonomous realm in which cultural processes unfold according to a guiding internal logic. The value placed upon 'newness' may derive from broader institutional contexts, but the cultural manifestation of this value is guided by the logic of an interrelated set of symbols and their behavioral correlates.

Lévi-Strauss on Formal Methods for Interpreting Myths

Contrast Kroeber's ambitions with those of the French anthropologist, Claude Lévi-Strauss. Lévi-Strauss is famous for his contributions to the original development of structuralism. Coming to the field a generation after Kroeber, Lévi-Strauss made a huge impact on anthropology by applying the principles of structural linguistics (and formal semiotics) to nonlinguistic matters of culture. Following in the path originally pioneered by Swiss linguist Ferdinand de Saussure and later by structural linguists such as Roman Jakobson (whom Lévi-Strauss met in New York during World War II while teaching at The New School), Lévi-Strauss used structuralist principles to analyze anthropological data on kinship structures and myths (Lévi-Strauss, 1963). Kinship structures are the single most important institution in traditional societies and Lévi-Strauss began his career by showing that structuralism provided a new way of interpreting the logic of kinship systems. Later he turned to the study of myths in traditional societies and it was especially here that we can see how Lévi-Strauss provides an early example of a social scientist seeking to use formal methods of analysis to approach what was an explicitly hermeneutic (or interpretive) research goal.

For Lévi-Strauss, the goal was to understand how the interpretation of a myth can be facilitated by analyzing the deeper relational structures (the bundles of relations linking concepts and actions within the myth). Lévi-Strauss saw that these structures provided an order for the content and the meaning of the myth, and ultimately it was the structural logic that made the whole greater than the sum of the parts. Specifically, Lévi-Strauss looked to develop analogues to the way that linguistic structures worked in language. Rather than investigating the 'morphemes' of language structure, however, Lévi-Strauss gathered up and analyzed the 'mythemes' (or 'gross constituent units' of meaning) that make up the content elements of myths.

In his essay on "The Structural Study of Myth," Lévi-Strauss illustrated this approach by deconstructing the Oedipus myth. Lévi-Strauss' technique depends on breaking the myth into simple sentences (or 'statements') and then looking for

commonalities in the semantic functions that each sentence performs. In the case of the Oedipus myth, the statements are semantically (and thus structurally) divided into common bundles of relations. Thus Lévi-Strauss' interpretation of Oedipus: "The myth has to do with the inability, for a culture which holds the belief that mankind is autochthonous [born from the earth], to find a satisfactory transition between this theory and the knowledge that human beings are actually born from the union of man and woman. Although the problem cannot be solved, the Oedipus myth provides a kind of logical tool which relates the original problem – born from one or born from two? – to the derivative problem: born from different or born from the same? By a correlation of this type, the overrating of blood relations is to the underrating of blood relations as the attempt to escape autochthony is to the impossibility to succeed in it" (p. 216).

Lévi-Strauss' approach is hermeneutic in the sense that his goal is to employ this style of cultural analysis to facilitate his interpretation of the meaning of the myth. It is formal because he gathers up data about the content of myths, he measures the distribution of the mythemes and the relations between them, and he provides us with an analysis (based on a system of Boolean transformations) that provides us with a plausible reading of one meaning of the myth. It is explicitly through his linking of the analysis of patterns in his collected data to his research goal of interpreting the meaning of the myth that Lévi-Strauss provides what is an especially useful example of a hermeneutically oriented approach to formally measuring cultural data. But, as Pierre Bourdieu would later show, Lévi-Strauss' structural approach to culture leads to a largely disembodied mapping of meaning, overlooking the important lived territories and material conditions that shape meanings and give rise to various symbolic struggles.

Developments of Cultural Measurements in Sociology through Community Studies and social Work Theory

In the early years of professional social science, there were a variety of quite different programs of research that sought to develop formal measures of culture. One stream of work developed out of the efforts to conduct neighborhood surveys such as those that were being used by Charles Booth to study the London slums in the late-1890s. These ideas were later applied (in 1896) by W.E.B. Du Bois in his survey of a black neighborhood of Philadelphia, which was followed by the Pittsburgh survey of 1907 (and dozens of other city surveys that came after that). These were intensive collections of data, even though the procedures were not the same as what we might imagine when we think of a modern, systematic, door-to-door canvassing with a survey questionnaire. "Rather it was an effort to provide an inventory and an overview of the state of the city, for which the investigators were omnivorous in their methods of data collection" (Converse, 2009[1987]: p. 24). Much of the data came in the form of the schedule, which "in the hands of the social surveyors was an instrument for making observations or for conducting interviews with respondents, or a mixture of both" (Converse, 2009[1987]: p. 34). With funding from the Russell Sage Foundation, the Pittsburgh initiative had 74 field staff compiling a mass of detailed information about all kinds of social phenomena. For example, the checklist for observing clothing worn by inhabitants included categories for, "spotted … dusty … torn … worn … patched … mussed … wrinkled …" (p. 34). Researchers compiled information by collecting "case-history interviews, which were gathered and then counted and compared among some dimensions, thus providing a 'casemounting' that represented a merger of the case study and statistical methods" (p. 34). But, as Bulmer points out, "the Survey used quantitative data in more of an exploratory and descriptive than analytic way" (1996: p. 18). Here and elsewhere, "It was as if there was an intuitive sense of the value of collecting extensive data about individuals in the population being studied, without the necessary knowledge either about sampling or how to handle the data once collected other than to compute simple counts of characteristics and then treat respondents on a case-by-case basis" (p. 26).

A different force for developing measures of culture came from another wing of the professional social work community. While community workers (including settlement house workers) had been visiting and surveying slum residents since the mid-1880s, by the turn of the century social workers were becoming more professionalized, and this included a strong push to rationalize and quantify social workers' field observations and to use those data in productive analytic ways. From her post as director of the Charity Organization Department at the Russell Sage Foundation, Mary Richmond (1917) sought to promote a style of professionalization in the field of social work that was explicitly modeled after the medical profession. Social workers were encouraged to gather systematic data from their cases in order to create a coherent system of data about behavior, character, and culture that could be used for diagnosing and treating the social pathologies that lead to poverty and ruin.

Meanwhile, professional sociologists were also studying communities. One of the most important of the early studies was the research collaboration between W.I. Thomas and Florian Znaniecki (1918) concerning the lives of Polish immigrants. Drawing particularly on letters written to and from family members in Poland, they emphasized the utility of using these types of documents for sociological research. "We are safe in saying that personal life-records, as complete as possible, constitute the perfect type of sociological material, and that if social science has to use other materials at all it is only because of the practical difficulty of obtaining at the moment a sufficient number of such records to cover the totality of sociological problems, and of the enormous amount of work demanded for an adequate analysis of all the personal materials necessary" (Thomas and Znaniecki 1958: 1832, as cited by Łuczewski, 2009).

Using these materials, Thomas and Znaniecki combined their intellectual interests. Thomas was mostly focused on attitudes while Znaniecki was concerned with values, but together they produced a solid grounding and advance for social science's understanding of how to analyze cultural forms. Łuczewski (2009) points out that for Znaniecki "The great mistake […] was to treat the problems of values […] as ultimate and self-sufficient, instead of taking them only as starting-points of future investigations." Thus he described values on two levels: content (ability to become an object of experience either sensual or imaginative) and meaning … In his relational perspective, meaning of a given value depended on its relations

with other values. Simply put, the meaning is the relation (2009, p. 8). These studies helped early on to situate the formal analysis of culture within the lived experience of groups seeking to use culture to achieve practical ends. This more Pragmatic view of culture, and thus the reasons for measuring cultural artifacts, resurfaces much later in the work of Pierre Bourdieu, which we discuss below.

Surveying Values, Attitudes, and Opinions

The invention of attitude measurements provided the means to use sample surveys to measure cultural content systematically. Not long after Thomas and Znaniecki published their work (1918), both Floyd Allport and Emory Bogardus published independent methods for formalizing the study of attitudes through the use of 'attitude scaling.' Later, Thurstone, Likert, and others produced rapid advances in the use of social surveys for measuring subjective experience, including cultural orientation, values, systems of meanings and beliefs, and subjective understandings of social situations (Converse, 2009[1987]). These developments coincided with the emergence of independent polling bureaus and university centers that conducted independent surveys, as well as the growing sophistication of population sampling and statistical methods for gauging significance and for interpreting scales measuring subjective experience. This includes cultural orientation, values, systems of meanings and beliefs, and subjective understandings of social situations (Converse, 2009[1987]).

World War II was a critical juncture. It brought academics together into large, multidisciplinary, state-funded research teams. In the case of survey research, Samuel Stouffer led a team of social scientists who surveyed over a half million U.S. Military personnel through the war years. Surveys asked about complicated matters like troop morale, racial integration, and officer performance. By the end of the war, survey methodologies had been improved and their legitimacy had been secured. Over the course of the next two decades, social scientists like Paul Lazarsfeld (Director of the Columbia Bureau for Social research) helped to build up the conceptual, theoretical, and practical foundations of modern social survey science, writing essays, and commissioning papers about how to construct effective survey questions, how to use the data to build variables, how to use cross-tabulations to compare variables, how to assess statistical significance and to run regression models, eventually establishing survey research as the new "language of empirical social research" (Lazarsfeld, 1968: p. vii).

Survey research has continued to improve since those years, developing into what is the social sciences' most mature and essential means of collecting data about culture and social life (Schuman, 2008). In recent years, survey analysis methodologies have been undergoing a renaissance as new scholars have come to the field and challenged traditional assumptions. Steve Vaisey (2009) helped to bring the dual-process model of information processing over from cognitive science, arguing that much of how people operate is indeed nonreflexive and driven by habit, but that other parts of human cognition is active and deliberative and that we should use our surveys more strategically to unearth these effects. Vaisey and Lizardo (2010) applied the dual-process model to look at how people's world views impact the character of the types of social networks that they form. Amir Goldberg's (2011) development of relational class analysis is another example of recent innovations in survey research. Instead of comparing respondents on the basis of having similar attitudes, relational class analysis emphasizes comparing respondents who have similar beliefs about the relations between attitudes.

Some Contemporary Approaches to the Formal Analysis of Culture

Measuring Meanings with Cognitive Science

Other areas of social science have also focused on the formal analysis of culture and meaning. In 1957, Charles Osgood (and his first two graduate students, George Succi and Percy Tannenbaum) published *The Measurement of Meaning*. The monograph introduced and demonstrated their efforts to use 'the semantic differential' as a tool for formally measuring the connotative aspects of word meanings. Their basic idea was to present respondents with a key word (such as 'father') followed by a series of paired opposites presented as seven point scales, happy/sad, hard/soft, slow/fast, and the respondent is asked to rank their association of the key word to each of the scales. Osgood and colleagues explain, "The semantic differential is essentially a combination of controlled association and scaling procedures. We provide the subject with a concept to be differentiated and a set of bipolar adjective scales against which to do it" (1957, p. 20). Factor analysis was used for simplifying the data. Of course a critical issue was identifying the right paired oppositions and these types of matters occupied Osgood and his colleagues for many years. Nonetheless, by the time the Snider and Osgood volume, *Semantic Differential Technique: A Sourcebook*, was published in 1969, the editors could report that "the semantic differential technique has gradually captured the imagination of psychologists…in recent years, hundreds of articles using the technique have appeared in professional journals" (1969, p. v). One direction these studies moved in was in the application of semantic differential tools to comparative studies of cultural meaning.

Much of the research by cognitive scientists tends to focus on the more cognitive and/or biological sides of cognitive processes. But these types of tools were quickly embraced by one group of anthropologists who had an explicit focus on culture, a story that is effectively told by one of the field's leaders, Roy D'Andrade (1995). About the time that Osgood and his colleagues were preparing to publish their book on meaning measurement, a pair of anthropologists, Floyd Lounsbury and Ward Goodenough, were publishing two new papers on the use of componential analysis, a method that was used to breakdown and analyze the core meanings of kinship systems (1995, 21). As D'Andrade explains, "The reason that the kinship terminology papers by Lounsbury and Goodenough had such a large impact was that they presented a rigorous method for identifying 'idea units' and analyzing the organization or structure of these units. While developed specifically for the analysis of kinship terms, it appeared that the general principles involved in identification and analysis could be extended to other domains. It was this body of methods and goals which was to become the agenda of cognitive anthropology" (1995, p. 17). By the mid-1960s this

field was growing. D'Andrade recounts the move from formal studies of kinship terms to a variety of studies of language terms (such as words for firewood) and from the use of simple schema toward more elaborate models for measuring cognition. DiMaggio (1997) provides an account of how studies in cognitive science intersect with research on culture.

Content Analysis

While the careful and ordered reading of texts goes back many centuries through various traditions of hermeneutics, the systematic treatment of texts as data in the more formal sense that we have employed in this article is relatively new. Harold Lasswell was an important contributor to these developments. After having studied the use of propaganda during World War I for his doctoral dissertation at the University of Chicago, Lasswell was well prepared to step into the position as director of the 'experimental division for the study of wartime communications, established at the Library of Congress during World War II' (Lasswell et al., 1949, 1952: p. 40). In this position he helped devise rigorous sets of procedures for coding textual material in a way that was intended to measure cultural and group-level discourse processes. After the war, Lasswell used these methods to coordinate a study of a corpus of 20 000 newspaper editorials sampled from 10 major newspapers (in five countries) between the years of 1890–1945 during which many of these conventions and strategies were published (Lasswell et al., 1952).

Content analysis tools continued to improve. Philip Stone and colleagues at Harvard (1966) developed the General Inquirer, which was a general purpose computer-based content analysis program that relied upon the building of specific dictionaries for various focused investigations. By the 1980s sociologists like Roberto Franzosi (1989) were using semantic grammars as a way to code the meaning of texts. These formal methods and project styles come together especially well in John Markoff's (1996[2004]) analysis of the origins of the French revolution (which builds on collaborative work done with Gilbert Shapiro). Drawing upon rich textual material preserved in the *cahiers de doléances* (the official lists of grievances drawn up in 1789 by rural communities, and others), Markoff is able to follow the flow of discourse back and forth between the legislators and the peasants across both time and space. Here the texts are interpreted with the help of formal tools and the lessons that are learned imply changes in how we now understand the role of the peasantry within the system of discourse and political maneuver around the years of the revolution.

One of the most productive offshoots of the content analysis tradition has been in the area of scientometrics – that is, a branch of formal analysis concerned with the sociology of knowledge and its measurement in research publications. A key component of this lineage is citation studies as represented, for example, in the many achievements of Loet Leydesdorff (2001) and his colleagues. This perspective also reflects an early blending of text analysis and network analysis, as authors, articles, and even journals are analyzed through the networks they form in coauthorships and cocitations. Still, in a number of ways, research projects in this field are being supplanted by new problems and new methods coming from the developments in computational analysis that are now being incorporated into fields like sociology, linguistics, and the humanities (see below).

Cultural Capital Studies

In a sense the French sociologist Pierre Bourdieu was foundational to the modern use of formal methods of cultural analysis in several important ways. One way was in the stream of research concerning the role of culture in social stratification and especially research surrounding the concept of cultural capital (Bourdieu and Passeron, 1977). The original insight was linked to the argument that participation in forms of high culture was a mechanism by which elite households were able to pass along hidden advantages to their children. Children from privileged households are inculcated with elite styles of cultural knowledge and forms of practice that enable them to display the required levels of what Bourdieu and his colleagues call cultural capital. The key insights here – that culture was a resource, one that was associated with mechanisms of class reproduction, and that these forms of cultural mastery could be identified using standard survey techniques proved to be a powerful catalyst for new streams of measuring culture. Paul DiMaggio borrowed the notion of cultural capital from Bourdieu and used a factor analysis to construct a set of measures of cultural capital that proved to be effective in predicting success in both educational and marital attainment (DiMaggio, 1982; DiMaggio and Mohr, 1985). Both the DiMaggio research and the ongoing stream of work by Bourdieu himself led to the production of a wide stream of research concerning the effects of cultural capital on stratification outcomes in different countries and across different institutional systems (e.g., DeGraaf et al., 2000; Kane, 2000; Roscigno and Ainsworth-Darnell, 1999; Van Rees et al., 1999). One especially influential reformulation grew out of a classic paper on the phenomena of 'cultural omnivores' by Peterson and Kern (1996) showing that increasingly, high-status culture consumers focused less on specializing entirely on exclusive cultural tastes and instead began to acquire a broad set of cultural engagements.

More recently, this field of work has morphed again as a range of new projects on measuring the relationship between culture and social structure have begun to take center stage. Omar Lizardo (2006), for example, using data from the General Social Survey, finds that measures of cultural tastes predict an individual's network style. Specifically, individuals with higher levels of culture participation are found to be more likely to have a greater number of strong network ties, whereas engagement with popular culture tends to be associated with larger weak-tie nets. The general sense here, as articulated in an important essay by Pachucki and Breiger on *cultural holes* (2010), is that scholars are increasingly coming to pay attention to how it is that culture acts as a general social resource that leads to the creation of things like social networks, thereby inverting the more traditional assumption that it is networks, which are primary and culture that is epiphenomenal.

Field Theory

A second important legacy of Bourdieu's research program is the recent growth in what is known as field theory. The idea of

describing social situations as being defined by 'field effects' goes back to several sources. The Berlin Gestalt psychology made famous the notion of fields in structuring perceptions. In social psychology, Kurt Lewin was instrumental in developing models of how to formally model social fields. Lewin himself drew upon the time he had spent with the Gestalt scholars and also the German philosopher Ernst Cassirer during his years at the University of Berlin. Borrowing also from physics and especially Einstein's conception of fields, Lewin (1951) sought to measure cultural phenomena by applying the idea of a field to an understanding of socially constructed interactional space. Much of his work drew upon studies of children's behavior conducted during his years as director of the Child Welfare Research Station at the University of Iowa.

Lewin began to use the field concept to construct models of an individual's 'life space,' which he described as "the person and the psychological environment as it exists for him" (1951: 57). These were essentially cognitive maps of individual's choice situations. They included "specific items as particular goals, stimuli, needs, social relations, as well as more general characteristics of the field as the atmosphere (for instance, the friendly, tense, or hostile atmosphere) or the amount of freedom." The definition was pragmatic. The life space included within it "everything that affects behavior at a given time" (1951: 241). The key goal for Lewin was to bring a level of formal analysis to the study of social psychology. Field theory worked well because of the type of mathematics that defined it. Inspired by the work of the German philosopher Ernst Cassirer on relationalism versus substantialism, Lewin was convinced that life spaces were essentially relational systems. Objects in the life space stood in particular relation to one another but their location could not be defined in precise metric terms. It was impossible to specify precise dimensions, linear measurements, or definable coordinate systems within which objects could be located inside an individual's life space, but field theory provided a way to measure these things in the purely relational sense of topology theory. Extensions of Lewin's ideas about measurement theory found their way into modern social network analysis, which is like Lewin's field space in that it is based on purely relational measures (Mohr, 2013).

Later in his career, Pierre Bourdieu began to focus on the study of fields, a term he used to designate "relatively autonomous social microcosms" corresponding to regions of institutional life. For example, Bourdieu studied the fields of art, academia, religion, and law. Each field is understood to be defined by a set of social relationships and a shared collective understanding about the meaning of what goes on inside the field or, as Bourdieu puts it, each field consists of "spaces of objective relations that are the site of a logic and a necessity" (Bourdieu and Wacquant, 1992, p. 97). Like Lewin, a primary reason that Bourdieu adopts a field approach is that it made it easier to theorize and measure social life and especially matters of culture. As Bourdieu explains with respect to his preference for correspondence analysis models, "if I make extensive use of correspondence analysis, in preference to multivariate regression for instance, it is because correspondence analysis is a relational technique of data analysis whose philosophy corresponds exactly to what, in my view, the reality of the social world is. It is a technique which 'thinks' in terms of relation, as I try to do precisely with the notion of field" (p. 96). Bourdieu (1984) famously employed correspondence analysis techniques in his studies of the association between social class and cultural tastes in France.

Field theory therefore brings together the embodied agency of actors and the meaningfulness of relational systems that enable and constrain action. The formal analysis of culture – the arraying of categories and identities in some relational space defined by those participating in these cultural forms – therefore reveals a state of the struggle for positions and dominance according to the underlying logic of a field. Inspired by Bourdieu's research, a number of other areas of social science have spawned studies of field. Institutional theorists in organizational studies have focused on studying fields (Powell and DiMaggio, 1991; Fligstein, 2001; Fligstein and McAdam, 2012; Martin, 2003; Padgett and Powell 2012). Within this group, a strong emphasis on cultural analysis has emerged among those who study organizational fields as being fundamentally grounded in a system of meanings described as institutional logics (Friedland and Alford, 1991; Friedland et al., 2013; Thornton et al., 2012).

Networks and Culture Perspective

Paul DiMaggio argues that "network analysis is the natural methodological framework for empirically developing insights from leading theoretical approaches to cultural analysis" (2011, p. 286). He goes on to suggest that "Social scientific work on culture has three analytic foci: formally organized systems that produce and distribute cultural products; expressive symbols that facilitate the production of individual and group identities and intergroup boundaries; and the symbolic organization of meaning. Relational theories are central to each of these topics" (DiMaggio, 2011, p. 286).

The interest in relationality comes up again and again in these research projects and this is partly a reflection of the common lineages of the work. Jacob Moreno observed network effects in his study of small groups during the 1930s, providing the first real example of modern network analysis. But Kurt Lewin's work on field theory was also connected to the emergence of modern network science. One link occurred through the work of Lewin's student Alex Bavelas (1950) who applied ideas from Lewin's hodological analysis of field space to assess the properties of networks. Later, Lewin's ideas were recast in graph theoretic terms by Dorwin Cartwright, Lewin's successor as Director of the University of Michigan Research Center for Group Dynamics (Harary et al., 1965; Mohr, 2013). Network theory also has deep connections with formal traditions of kinship analysis that were being conducted by anthropologists (Breiger, 2004). Indeed, Harrison White who went on to become the leading figure in social network analysis in American sociology during these years started out his career in sociology in part due to his fascination with Lévi-Strauss' work on kinship algebras (White, 1963).

In its early years (1960s–1970s) the sociological field of network analysis was explicitly anticultural in its approach, the feeling being that network ties were material, concrete, and measurable, while culture was none of those things. But by the early 1990s that sentiment had begun to change. Harrison White made a pivot toward culture when he published the first edition of *Identity and Control* (1992) in which he lays out an

expansive theory of social life that relied quite explicitly on theorizing the intersection of culture and networks. Karen Cerulo (1988) had already been working on matching semiotic theory with the empirical analysis of data from cultural artifacts that included visual symbols and written music. A number of other scholars had begun merging social network methodologies with the analysis of cultural data. Carley (1994) used network models to analyze the meaning structure of science fiction novels, Bearman and Stovel (2000) used network graphs to analyze narrative structures in Nazi party members' life stories, and Smith (2007) did something similar with people's narratives about conflicts they have lived through in Istria. Network analysis reveals how some narrative elements can link disparate narrative structures together as a kind of cultural bridge.

Much of this work makes use of two mode data, meaning that relationships are examined that span across two categories or domains of things – relations that link individuals and groups, members and committees, or categories of persons and categories of treatments. Breiger (1974) did the original work on this in his development of a formal model for analyzing the linkages between individuals and groups as a structural duality. These types of cultural models were then used by Mohr and Duquenne (1997) when they analyzed the implicit institutional logic of nineteenth-century poverty directories with Galois lattices to assess how organizations matched categories of poor with poverty treatments regimes. Mische and Pattison (2000) also used lattices as a way to analyze the duality between Brazilian youth organizations and their projects, which they define as "evolving, imaginatively constructed configurations of desired social possibility, accompanied by an implicit or explicit theorization of personal and∼or collective capacity to act to achieve that possibility." Yueng (2005) uses lattices to compare members of different communes according to the types of ways that commune members characterize their relationships with one another. Martin (2000) compares the kinds of animals and the types of occupations that they hold in children's books of Richard Scarry.

The New Computational Approach to Culture

Computational Linguistics

Linguistics has long been more scientifically advanced than the other social sciences in the sense that more progress has generally been made in understanding the basic rules and principles of linguistic operations, and much of that is due to the elaboration of sophisticated theories and methods of structural analysis of language systems. But with the rise of the digital society, linguistics has also become both a data science (dedicated to processing large amounts of textual data) and an engineering science focused on trying to create useful technologies.

Whether linguistic projects of cultural analysis are also grounded in hermeneutic styles of culture analysis depends. In some sense, all of linguistic science has an interpretive goal since it is all geared toward analyzing and understanding language and speech activity. But, on the other hand, there are also many different levels and styles of understanding in linguistic science. Syntax tries to account for language use at the level of the sentence, while semantics and pragmatics deal with the relation between these lower-level language processes and the broader problems of meaning and language use. Moreover, modern linguistic science has moved well beyond purely structural analysis. As Hajic (2004) notes, "Today we can say that one of the turning points for linguistics was Claude Shannon's work (1948)" (p. 80). Shannon provided the research that lays out the grounding for modern communication theory. It was built upon a long tradition of mathematical equations that had been developed to manage the engineering of telegraph signals. Shannon and Weaver introduce their formulation by writing, "The fundamental problem of communication is that of reproducing at one point either exactly or approximately a message selected at another point. Frequently the messages have *meaning*; that is they refer to or are correlated according to some system with certain physical or conceptual entities. These semantic aspects of communication are irrelevant to the engineering problem. The significant aspect is that the actual message is one *selected from a set* of possible messages" (1949, p. 3). Shannon's approach to communication theory has come to provide one foundation for how engineering researchers such as computer scientists approach the measuring of culture, through the use of stochastic based models, an issue that turns out to have relevance in other fields of computational social science today.

Applied computational linguistics today is divided into a number of subspecialties, "on the analysis side it deals with phonetics and phonology (sounds and phonological structure of words), morphological analysis (discovering the structure of words and their functions), tagging (disambiguation of part-of-speech and/or morphological function in sentential context), and parsing (discovering the structure of sentences; parsing can be purely structure-oriented or deep, trying to discover the linguistic meaning of the sentence in question). Word-sense disambiguation tries to solve polysemy in sentential context, and it is closely related to lexicon creation…Language modeling (probabilistic formulation of language correctness) is used primarily in systems based on stochastic methods" (Hajic, 2004, p. 82).

All of these technologies provide powerful tools for social scientists seeking to analyze meanings in texts. One of the technologies that is already finding fast adoption among social scientists are topic models. The most important of this class of stochastic models is latent Dirichlet allocation (LDA) introduced by Blei and colleagues (Blei et al., 2003). This is a method that provides an automated procedure for coding the content of a corpus of texts (including very large corpora) into a set of substantively meaningful coding categories called 'topics.' The algorithms work with little or no human intervention. Instead of beginning with predefined codes, the researcher begins by specifying the number of topics for the algorithm to find. The program then identifies that number of topics and returns the probabilities of words being used in a topic as well as an accounting of the distribution of those topics across the corpus of texts. While not infallible, when used thoughtfully and applied carefully, the method seems to consistently yield very plausible readings of the texts, demonstrating what DiMaggio et al. (2013) describe as high levels of 'substantive interpretability.' Natural Language Processing tools are another class of text analysis tools that should be of interest (for an example,

see Mohr et al., 2013). Bail (2014) provides a useful overview of the range of tools from computational linguistics that are of use to social scientists who want to study culture.

Information Sciences

The digitalization of numerous types of texts and archival records has led to the increasing demand for quick and efficient information search and retrieval – and, thus, revitalized the interdisciplinary field of information science. With respect to the formal analysis of culture, information science scholars most closely resemble their colleagues in computer science – that is, the research program is one focused upon developing automated tools for quickly (and efficiently) processing and summarizing the content of a large amount of textual data. The purpose is not to understand culture within a broader theoretical framework of human behavior, but to create rapid-fire queries that extend scaling and clustering techniques to more readily handle very large corpora. Salient examples include the work of Katy Börner and colleagues who have developed a number of appealing visualization technologies applied to texts (e.g., Börner et al., 2005). Social scientists have picked up on some of these tools, and developed their own, in ways that are more theoretically informed. Kathleen Carley and colleagues, for example, have worked closely across technical and social science disciplines in producing a suite of tools for optimizing organizational communication and performance. This work is grounded in network and organizational theories, and can therefore be considered a line of work that is consistent with paradigms at the center of operations research or management science – that is, scholars may create more optimal and rational complex organizations. This is done in part by seeing an organization as a type of machine or system in which an integrated circuitry of contact and communication is essential for proper goal attainment. To the extent that culture and *meanings* (i.e., interpretations) are essential to the day-to-day workings of and long-term learning within a complex organization, information science scholars play a vital role by developing tools for quickly retrieving and summarizing such qualitative data through a number of reduction techniques. Of course, once created, these tools are available for adapting to projects seeking to build upon theories of culture as it pertains to understanding and predicting human behavior.

Computational Humanities

In a sense, the humanities were a natural place to bring computing together with the study of culture. Early work by Roberto Bursa, for example, who, beginning in 1949, began creating the first computer-based concordance of the writings of Thomas Aquinas was carrying out a style of work, which was in many ways a logical extension of the very sort of systematic archival analysis and inking that biblical scholars had been doing for centuries. Similarly, there was a natural adaptation of classics studies to the computer analysis of texts, precisely because scholars in the field were already used to thinking in terms of carefully classified and categorized bits of information (Crane, 2004). However, the digital humanities movement has really accelerated over the last decade or so as massive quantities of digital texts began to become available.

An article published in *Science* by Michel et al. (2011) captured something of the excitement about this new state of affairs. The essay, *Quantitative analysis of culture using millions of digitized books* drew upon the availability of digitized texts in the Google Books project. In this case, over 5 million books (in multiple languages) were included in the database, a number that according to the authors, represents about 4% of all the books ever published. The corpus contains over 500 billion words and the authors use this material as a means for marking off what they call the new science of Culturomics, defined as "the application of high-throughput data collection and analysis to the study of human culture" (p. 181). Although the corpus itself is extremely large, the actual analysis of these 5 million texts was fairly simple, the authors focused on identifying the most frequent n-grams (clusters of words) and then tracking their distributions across time.

There are other contributors to this field who are themselves accomplished humanist scholars who have begun using the availability of digitalized texts as an opportunity to continue a more traditional humanistic style of research, but to do so through a decidedly different observational lens. Franco Moretti, for example, Director of the Stanford Literary Lab, has recently published a new book entitled *Distant Reading*, an obvious nod to the traditional style of literary methodology known as 'close reading.' In this book (and in the series of downloadable SLL pamphlets), Moretti recounts a number of the ways in which he and his colleagues have effectively transformed the kinds and styles of research questions that they pursue as a response to the new opportunities of pursuing 'distant readings.' This includes, to cite just one example, the development of automated procedures that can be used to transform a corpus of thousands of dramas and plays into network graphs (in which speakers are connected in these graphs to other speakers with whom they share direct dialogue). Describing his analysis of Shakespeare's play *Hamlet* using these techniques, Moretti writes, "You see the possibility here: different uses of language emerging in different network regions. Style, integrated with plot as a *function* of plot. It would be a breakthrough, and not just for literary analysis – but for the analysis of culture more broadly" (p. 229).

Computational Sociology

The rise of digital information also is relevant for a variety of emerging new projects among sociologists interested in measuring culture. Bail (2014) tells us, "More data were accumulated in 2002 than all previous years of human history combined. By 2011, the amount of data collected prior to 2002 was being collected every 2 days" (p. 465).

To take one example, Brian Uzzi and his colleagues (Saavedraa et al., 2011) collected information from commercial day traders, a task that they were able to do remarkably easily given the fact that all of the relevant information about every transaction, including all e-mail and text conversations with clients, was automatically recorded and stored as a part of the modern way of conducting business. By measuring the meaning of texts written (using automated sentiment analysis algorithms) and correlating those

measures with real-time performance measures, every trade made, the value of the trade obtained, and the possible value of that trade, Uzzi and his colleagues are able to directly connect the style and the tone of a trader's conversations with the rationality (as measured by money earned) of that trader's performance.

It is the ready availability of digital data that makes all the difference here. Social scientists have traditionally been severely hampered by the difficulties of designing, gathering, and analyzing social data. Now clever researchers have the ability to turn toward the simplicity of our new digital lives to their advantage. For another example, McFarland et al. (2013) take advantage of this in their study of speed dating encounters by using digital microphones and other types of real-time data gathering devices whose output can be formally measured and analyzed in order to provide a far richer record of (in this case) the many small cues, intonations, and emotional markers that characterize everyday interactions.

Bail (2014) provides an overview of the types of digital data sources that are becoming available for use as well as an assessment of the many kinds of algorithmic tools and measures that computational researchers have developed to facilitate the exploration and analysis of large-scale text corpora and the Internet network systems. He reports that there are a great many opportunities as well as a number of definite drawbacks to simply making use of computational tools that have been designed and crafted by scientists and engineers with very different ambitions and goals. Here, we are reminded again of the wisdom of Ernst Cassirer who warns us that any attempt to measure culture will be dependent upon our conceptual framework for theorizing culture. Cassirer writes, "Everywhere physical thought must determine for itself its own standards of measurement before it proceeds to observation …. It is not clocks and physical measuring rods, but principles and postulates that are the real instruments of measurement (Cassirer, 1923: p. 364–365).

Abstract

Michel Foucault is one of the most influential, and also most controversial, social thinkers of the century. His work represents a sustained effort to reconstruct the way in which the specifically modern Western form of subjectivity has become what it is through the institutionalization of techniques of self and practices of truth-telling, and the will to truth and knowledge.

Foucault's Intellectual Trajectory

Foucault was born on 15 October 1926 in Poitiers, France. His upbringing was organized around knowledge since his early childhood (he started to attend school at the age of three), and major political events, especially wars (the Ethiopian War, the Spanish Civil War, and World War II), also had a major impact on his formation. In September 1945, he moved to Paris where he listened to the lectures of Jean Hyppolite during a preparatory high school year, and was then admitted to the prestigious Ecole Normale Supérieur. These were troubled years for Foucault, intellectually, personally, and politically alike. He had a short spell with the Communist Party and had difficulties in managing his homosexuality (Eribon, 1991).

After graduating in philosophy in 1951, he received further qualifications in 1952 and 1953 in psychopathology and experimental psychology. He then started teaching, working on his thesis, and also attending the St. Anne psychiatric hospital. However, under the effect of an intensive reading of Heidegger and then especially Nietzsche, his interests gained focus, and he decided to leave the standard academic career, even the country.

Between 1955 and 1960, Foucault worked as a cultural diplomat, first in Uppsala, Sweden (at the invitation of Georges Dumézil), then in Warsaw, Poland, and Hamburg, Germany. He thus experienced personally the different economic and political regimes of the period, noticing their latent similarities, and also worked on his doctoral thesis. This was defended in 1961, under the supervision of Georges Canguilhem, and published as *Folie et déraison* (Foucault, 1961) (*Madness and Unreason*, republished in 1972 with a new preface as *Histoire de la folie*, or *History of Madness*) with the support of Philippe Ariès.

After completing the book, Foucault continued his work on the reconstruction of the joint emergence of modern forms of scientific (especially medical) knowledge and its institutional context, and published in 1963 *The Birth of the Clinic* (Foucault, 1963). At the same time, he also became increasingly involved in literary criticism, publishing various essays and a book on Raymond Roussel. As a result, he came to 'bracket' institutional practices temporarily in his work and turned toward language and discourse – a shift he would later much regret. The result was *The Order of Things* (Foucault, 1966). Published in 1966, at the height of structuralism, the book immediately became a huge success, identifying Foucault as a main protagonist of the field.

Becoming increasingly uneasy with this label, Foucault soon embarked on a major self-reflexive exercise, attempting to clarify his project and its underlying methods for others and for himself. This eventually led to *The Archaeology of Knowledge* (Foucault, 1969) and a series of major methodological papers. At the same time, he moved from Paris to Tunis, where he lived during the events of May 1968. However, instead of a systematic and final clarification, the reflexive exercises rather brought about a major reorganization of Foucault's entire work. Appointed as Chair of the History of Systems of Thought at the prestigious Collège de France, a few months after his inaugural lecture, Foucault suddenly shifted his intellectual interest from knowledge to power, and at the same time he became engaged in political struggles as the founder of GIP (group for information on prisons).

His new interests led to the publication of *Discipline and Punish* (Foucault, 1975), easily his most widely read and influential work. However, around the time of its publication, Foucault was again already reflecting on his work. This yielded a book-length study published as the first of six planned volumes on the *History of Sexuality* and a series of significant and quite influential interviews and shorter pieces (see Foucault, 1980b). But perhaps most important, it led to another major reorientation of his project. When trying to specify the main characteristics of his approach to the study of power, he eventually came to realize that the question of power was not central to his work. This change – often interpreted as Foucault's 'crisis' – is visible in successive displacements of the time horizon of the work, first to the fifteenth and sixteenth centuries, then to early Christianity, and finally to Greco-Roman antiquity; and also in a reorganization at the level of central concepts: from power-knowledge to government by truth; from the genealogy of power to the hermeneutic of the subject; from technologies of power to techniques of self. It was strongly influenced by Foucault's encounter with the works of major scholars of antiquity, such as Pierre Hadot and Peter Brown. At the same time, he also increasingly recognized affinities with the works of social scientists like Norbert Elias and especially Max Weber. These encounters, together with a systematic reflection on the trajectory of his past work, helped Foucault identify the underlying problem of his work as being concerned neither with power nor with discourse, rather with the link between truth and subjectivity (Foucault, 1997: 281).

The new orientation is clear in the published volumes two and three of the *History of Sexuality* project (Foucault, 1984a, 1984b), which discuss the way practices related to pleasure were problematized in ancient Greece and Rome, respectively.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61035-8

Volume four, covering early Christianity, and written before the published volumes two or three, exists only in the form of an uncorrected manuscript, as Foucault was hospitalized, terminally ill, just days after he started to revise it for publication.

The best guides for the last, arguably most significant period of Foucault's work are the courses he gave at the Collège de France between 1978 and 1984, especially the last two courses on parrhesia or frankness of speech and truth-telling. Foucault died in Paris on 25 June 1984.

The Work and Its Context

Throughout his writings, covering over three decades, Foucault's work focused on the reasons and manner in which the individual subject, especially its 'true being,' has become the center of attention in the pursuit of knowledge and the search for social order, considered as an evident starting point and foundation. Thus proceeding, Foucault posed questions on what has been taken for granted by the main available approaches in philosophy and the social sciences, without dismissing them as mere ideology or illusion. This explains much of both the dynamics of Foucault's intellectual trajectory (discussed in this section) and its reception (covered in the next).

The trajectory has three major peculiarities. First of all, far from following a straightforward path of development, it was quite bumpy and curvy, progressing through crises (see Szakolczai, 1998). This was probably unavoidable, as Foucault's work did not simply represent an addition to the existing stock of knowledge nor a general attack on it; rather it was a problematization of the taken for granted. Furthermore, and for much the same reasons, the trajectory cannot be separated from the substance of the ideas. Given its detours, it would seem particularly desirable to get over such details and focus on the main results. However, this would undermine the effectivity of Foucault's undertaking, as doing so one would fail to problematize one's own hidden related preconceptions. Finally, Foucault was quite aware of the pitfalls of his project, and throughout his career kept reflecting on its directions and stakes. These reflections had a significant effect on the trajectory and contain a concise introduction to Foucault by Foucault, a starting point for any interpretative effort.

For these reasons, the exact mapping of Foucault's early steps is of crucial relevance, as this not simply defines the starting point of the investigation that would later be assumed as given, but also indicates the way in which Foucault plunged into the questioning and mapping of the aspect of the taken for granted he singled out for attention as problematic. The first anchor point to be questioned was academic philosophy that assumed, from Descartes through Kant to Husserl and Merleau-Ponty, that the 'subject of knowledge' or the 'transcendental ego' was the starting point of any philosophical undertaking. Foucault recognized that behind the epistemological assumptions of this approach there lay an entire anthropology, and was particularly interested in Kant's related work, which he translated and introduced as his minor thesis.

Given his problems with academic philosophy, he turned to psychology, or an empirical approach to the Kantian question: What is man? At the same time, he experimented with the two main alternative theoretical frameworks to academic philosophy, Marxism and psychoanalysis, finding them unsatisfactory. It is this combination that underlies the profound significance and originality of Foucault's work. His background incorporates both theoretical and empirical work: the philosophy of the subject in its various kinds and positivism on the one hand, and their main critiques, the works of Marx and Freud on the other, while being orthogonal to this entire epistemological field.

In his attempts to go beyond the available approaches, Foucault found inspiration in the works of Heidegger and Nietzsche. Instead of starting from the experiences of the subject, gained through a combination of sense perception and the application of universally valid categories of mind, Foucault rather posed the question of how this subject has been actually historically formed through experience.

In his last writings, Foucault would argue that there are three main axes of experience: knowledge, power, and subjectivity. This conceptualization, however, was only the fruit of late reflection on his own work. In his first major book, *History of Madness*, all three axes were dealt with, and their separation was not at all clear-cut. Furthermore, instead of directly reconstructing the subject of knowledge, he started at the opposite end, as if following a reflexive strategy, by reconstructing the opposite or the mirror, the subject of nonknowledge or the nonsubject, the mad, the carrier of 'unreason.' The aim was to show that mental illness was not simply an objective aspect of the human condition that was there, waiting to be discovered finally by the methods of true science, but a complex form of behavior that was itself shaped by these very methods and their institutional context.

In this book and the follow-up work, *The Birth of the Clinic*, Foucault tied closely together the reconstruction of the views concerning the aim and methods of collecting knowledge about individual human beings and its context of closed or total institutions, or the knowledge and the power axis. This changed with his third main book, *The Order of Things*, where the institutional dimension or actual scientific and social practice was left out of the picture. On the one hand, this enabled Foucault to sharpen his tools here and in the following, reflexive work, defining his archaeological method as "an attempt to introduce the diversity of systems and the play of discontinuities into the history of discourses" (Foucault, 1991). On the other hand, however, this also meant a certain one-sidedness, the suspension of the study of the link between displacements in thought and broader historical processes.

As a result, in the 1970s, Foucault reversed his approach and turned to the power axis, developing conceptual tools like power-knowledge (which never meant a simple identification between knowledge and power, only the assertion of the impossibility of a complete separation) or the microphysics of power. This meant a shift of disciplinary allegiances from philosophy and the life sciences to sociology and the social sciences, and a reorientation of focus from the subject of knowledge of phenomenology to the liberal individual as a subject of rights, the taken for granted starting point of modern political and social theory. Here as before, Foucault chose an indirect approach, focusing his reconstructive historical work on the formation of the subject deprived of rights: the criminal.

Discipline and Punish not only returned Foucault's interest to institutional practices but also sharpened his analytical tools

concerning the power axis. However, if his work in the 1960s was somewhat affected by flirtations with literary criticism and structuralism, his new work overcompensated by showing too much affinity with the ascendant leftist, neo-Marxist vogue, most visibly at its often excessive rhetoric. Both the achievements and the problems of the work can be shown through its central term and most striking metaphor, the Panopticon, as symbol and embodiment of modern power. It is a circular building structure, where inmates are closed into individualized cells, with no possibility of horizontal communication, while the cells are fully transparent toward the central tower, occupied by the guards. Inmates cannot see whether they are under supervision, while everything they do is fully visible to the guards, resulting a trap of visibility. The idea is to achieve the internalization of supervisory gaze, thus instituting an efficiently functioning, automatic mechanism of power. While Foucault was often criticized for painting an excessively negative vision of an inescapable, omnipresent, and omnipotent power, more applicable to totalitarian states than liberal democratic societies, the full prevalence and significance of panoptical mechanisms can only be realized by recognizing that the Panopticon has the same spatial arrangement as the circus. This helps one to understand the nature of the power exerted by modern propaganda machines and the media, for which Foucault's work opened a path: such technologies of power perpetually switch between asphyxiating control and relaxing circus modes of operation, both being based on the same fixating of the gaze on the center, where time and again all-powerful guard-politicians reveal themselves as clowns, while the jovial antics of the buffoons in the center of media attention imperceptibly transmogrify themselves into demonic machinations.

Foucault's next series of works on sexuality were intended to continue and complement the studies of power-knowledge as started in *Discipline and Punish*. An account of the continuities and discontinuities between the project as announced when its first, reflexive, and methodological volume of the series, *La volonté de savoir* (unfortunately omitted from the English title), is fundamental for understanding the last and arguably most important period of Foucault's work. At one level, the differences are marked. In the years around 1980, Foucault again stepped back from his previous approach and undertook another major reorientation. This meant that while previously, whether focusing on knowledge or institutional practice, Foucault studied how certain human beings shaped other human beings as objects of power and knowledge, now he set out to analyze directly how individual human beings were driven to reflect on their own being as subjects.

This was accompanied by a marked change in style, even a refocusing of his entire project. While Foucault's aim so far was to render visible the singularity of the idea that the individual subject should be the foundation of knowledge and social order, now he recognized the seriousness of the problem to which this came to be the answer. The shifting focus of interest on the individual was an answer to the manner in which being has become problematized at a certain point, the way in which human beings came to pose question marks to 'what they are, what they do, and the world in which they live' (Foucault, 1984a: 16). While this turn on the one hand rendered visible the Heideggerian inspiration behind his work, on the other it also brought to the surface the close affinities between Foucault and Max Weber.

Yet, continuities were also fundamental, and these concern the persistent driving force underlining Foucault's interest in the 'problematization' – a crucial concept discovered in this period, in order to capture the manner in which a vague sense of unease is transformed into the concrete formulation of a problem – of sexuality. The understanding of the exact nature of such continuities and discontinuities is now possible, given that publication of Foucault's Collège de France lectures is under way (for studies using the material that was previously only available in the Foucault Archives, see McGushin, 2007; Szakolczai, 1998, 2003).

Foucault's (1976) book was motivated by a distancing from an increasingly dominant and seemingly self-evident discourse in the social sciences, and in public life in general, which on the one hand laments the presumed pervasiveness of sexual repression characteristic of the rising modern world, explained by referring to Victorian morality and capitalism, and on the other proclaims sexual liberation as a program, in particular through the free realization of one's true sexual identity. In contrast, Foucault argues that the problem lies rather with this discourse itself, and the will that animates it. This will is a form of the will to knowledge, which is best visible in modern legal and medical discourses, traced provisionally to the Christian practice of the confessional. Foucault's central claim, however, is that there is a basically positive connection between these two discourses, instead of a radical difference; and that both discourses hide, even mask, the more fundamental issue, which concerns the incitement rather than repression of desires. What is uniquely specific to the modern world is thus not the repression of sexuality, rather a continuous playing with scandalizing and seducing, with attractions, evasions, and 'circular incitements,' that constitute *perpetual spirals of power and pleasure* (Foucault, 1980a: 49; emphasis in original). The inciting of desires results in the constitutive investment and formation of sexuality, thus fixes human beings by their own purposefully incited passions into certain prefabricated categories of sexual identity, thus giving them "an analytical, visible and permanent reality" (Foucault, 1980a: 44). The sexuality that supposedly captures the heart and truth of one's being is therefore nothing else than the correlative of these discursive practices (Foucault, 1980a); with the "irony of this deployment (being) in having us believe that our 'liberation' is in the balance" (Foucault, 1980a: 159; last sentence of the book).

Foucault never retracted his position; the introduction to the second volume of the *History of Sexuality* project, a central summary of the work completed thus far and of his methodological approach, restates the same position about the invested and constructed nature of sexuality. However, as it can be reconstructed through the last five lecture courses of the Collège de France, the single most important trace of the movements in Foucault's thinking over his last period, he moved beyond the earlier position not by discarding it as erroneous, rather in the sense of gaining a further, magnitude depth.

The 1979–80 lectures dealt with obligation assigned to individuals concerning the manifestation of truth and the 'regimes of truth' that emerged in this regard. The title of the course, 'The government of the living,' was irrelevant for its content, as that title was provided before Foucault reoriented

his work. Such reorientation was marked by a long discussion of *Oedipus King* by Sophocles, revisiting the lectures given during the 1970–71 course. Regimes of truth were defined as the types of relations that exist between manifestations of truth and the accepted procedures to ascertain truth, and also the subjects that are the operators, witnesses, and eventually objects of such procedures. The course focused on three such procedures, central for early Christianity: baptism, penitence, and the examination of conscience. The next year's course, entitled 'Subjectivity of Truth,' was the only course explicitly discussing sexuality, situated now on the broader horizon of the links between individual subjects and truth. The course of 1981–82, entitled 'The Hermeneutics of the Subject,' continued to study the links between subjectivity and truth, but did so from the perspective of a next central concept, the 'care of the self' (in fact, the title again lags behind this significant semantic shift from 'subject' to 'self'). The course started with a long discussion of Plato's *Alcibiades*, introducing the central concern of the course, the contrast between the care of the self and the Delphi injunction to know yourself, understood as the two central principles defining ancient philosophy. The last two courses both bear the general title 'The Government of Self and Others,' and both are centrally about parrhesia, or the courageous practice of telling the truth. The course of 1983 systematically introduced the term, starting with a long analysis of Euripides's play *Ion*, and then discussing the relevant passages in Plato's dialogues, including *The Republic*, *Laws*, *Gorgias*, the *Apology*, and *Phaedrus*, and especially a long and important analysis of Plato's *Seventh Letter*. The 1984 course, also carrying the title 'The Courage of Truth,' continues the study of parrhesia. After a crucial initial discussion of the last words of Socrates, using Dumézil's just-then published interpretation, and Plato's *Laches*, most of the course focuses on the Cynics. While occasionally recognizing certain kudos in their acts, Foucault's discussion presents the activities of the Cynics as an exaggerated and excessive, thus a bad form of, parrhesia. The course closes with a very cursory discussion of Christian parrhesia.

All of these courses were introduced by lectures in which Foucault was reflecting on the main stakes of his work, its underlying unity, and the central problem it was exploring, providing a crucial running commentary on Foucault by Foucault, which eventually culminated in the published introduction and draft preface to the *History of Sexuality* (see in *The Foucault Reader*), or the essays discussing Kant's reflections on Enlightenment and the French Revolution. This running commentary not only adds crucial further details to these conclusive pieces, but also is necessary for understanding a thought in its movements, in its vitality, helping avoid a dogmatic and often out of context canonization, relying on a few simplified ideas, which can then be routinized and force-fed.

The directions opened up in these works can be resumed through three interconnected concepts. The first is the importance attributed to the term care, in particular in expressions like care of the self and the care for truth, present in prominent lecture, article, and interview titles of the past period. While previously Foucault had a more or less exclusively negative, critical angle on the will to truth and the formation of the self through true discourse, now he perceived in addition a significant legitimacy of a care of the self, in terms of an ethic and esthetic of existence that helps give a shape to and control over one's being, in order to resist the invasive influences of certain aspects of the social and political environment, and started to trace the historical source of such practices, so central to European culture, back to antiquity. This focus on care was part of a return to the thinking of Heidegger, one of his most important formative influences. The second implied a rethinking of the connection between the self and truth, through his new interest in the practice of truth-telling, traced back to the Greek concern with parrhesia, characteristic in particular of Plato's presentation of Socrates, and his political philosophy. The discovery of this practice and its significance is connected to a systematic rereading of Nietzsche (see in particular Nietzsche's discussion of the truth-teller in *Gay Science*, no. 343–345). Parrhesia (a Greek word meaning telling everything) is closely connected to the care of the self and its ethical stance. It means a courageous act of truth-telling, involving serious risks and danger to one's identity and life, the revealing of a truth that is based on personal conviction, concerning both the content of the statement and its significance. Foucault also discussed the ambivalence of the practice, as telling everything is, strictly speaking, impossible, and thus can be used to promote various agendas and masked games. Beyond ethical questions, this practice also has fundamental epistemological implications, brought out in particular in Foucault's very cursory discussion of parrhesia in Christianity (this was the last section of the course, with little time left; for details, see Szakolczai, 2003: 229–240). Modern science restricts truth to matters that can be repeated and confirmed through experiments. However, the most important aspects of human and social life are unrepeatable events, where the only source of evidence is buried in the mind and heart of human beings. The care for truth implies a need to restore a concern with the nature of such personal evidence at the heart of philosophy, uprooted from there since Descartes and Kant. Foucault's recurrent discussions of the shortcomings of Descartes are among the most precious gems in these lectures.

The third major concept, technologies of the self, concerns the manner in which these discoveries enabled Foucault to return to his lifelong preoccupation with the way in which the very identities of human beings are being tampered with and fabricated in the modern world. The care of the self relies on techniques by which individuals could master their own behavior in order to find a way to live harmoniously, and with dignity, under conditions of external adversity. However, these very techniques could themselves be taken up, organized, and manipulated for opposite purposes as well, thus becoming part of a technological machinery of power, aiming at a mechanical and quasichemical transformation of human beings. Many of Foucault's late lectures and interviews were concerned with the attempt to clarify this extremely ambivalent and complicated relationship between the care of the self and for truth on the one hand, and the technologies of self and individualization, the will to knowledge or truth, and apparatuses and machineries of power on the other. This line of research, just as the previous two, remained fundamentally incomplete, cut short by Foucault's death in 1984. Yet, the very presence of this project makes Foucault one of the most important thinkers of the last century, and arguably the most faithful heir to both Nietzsche and Heidegger.

The Foucault Effect

Foucault has been one of the most influential social theorists of the past decades. His works are widely read in all branches of the humanities and the social sciences, including philosophy, sociology, history, anthropology, cultural studies, and literary criticism. However, they have always been controversial and most probably will remain so in the future.

Both characteristics can be traced to the same source. Foucault's work developed not simply as a dissent from the then-ruling paradigms in philosophy and psychology, phenomenology and positivism, but was similarly critical, after some initial flirtation, of the undertakings of Marx and Freud. Based on his reading of Kierkegaard, Heidegger, and especially Nietzsche, Foucault went into directions that did not easily fit in the contemporary intellectual landscape. This led to a persistent problem of understanding, reception, classification, and (mis)labeling. It was only deepened by some strategic concessions Foucault made when trying to establish bridges between his lonely undertaking and the work of his contemporaries.

Foucault's work first gained wide currency in the mid-1960s when, after the publication of *The Order of Things*, he was considered a prime exponent of structuralism, together with Barthes, Lacan, and Lévi-Strauss. His archaeological method, aiming at the establishment of historical discontinuities at the level of discourses and considering texts written between two consecutive historical breakpoints as belonging to a discursive formation, governed by certain autonomous rules, is still influential in wide circles within philosophy and literary criticism. The work largely followed the footsteps of Foucault's earlier works, relying more on Dumézil, Canguilhem, and Bachelard than on Lacan or Lévi-Strauss. It was also different from the structuralist project and mentality, as it made no attempt at developing formal schemes with claims of general validity. Still, the label structuralist stuck due to the gestures Foucault made in its last chapter to the then-rising structuralist tide.

Though Foucault's work of the 1970s on power-knowledge came to be inserted in a different debate and exerted its impact on a different field, the modalities were remarkably similar. As a conscious break with his earlier work, *Discipline and Punish* aimed at direct political relevance and impact. While *The Order of Things* was critical of Marxism and took no side in the political landscape, the new work was clearly aiming at making contact with the far left and started by using a language heavily indebted to Marxism. As the work progressed, Foucault steadily retrieved his central interest in the formation of the self through true discourse, in this case the shaping of the criminal. However, in its style and rhetoric, the ballast was still present, and the work came to be read and regarded as a prime example of the post-structuralist and postmodern alternative to old-fashioned Marxism. While in the 1960s Sartre considered Foucault's work as the last rampart of the bourgeoisie, his work of the 1970s served as a lifebuoy for many on the sinking boat of the radical left.

Soon Foucault became just as deeply disturbed by this reception of his work as with the structuralist label in the 1960s. His self-reflexive exercises of the late 1970s and the early 1980s not only helped him to regain focus in his own work but also to find, at the end, after some flirtation with the thought of the Frankfurt school, the most fruitful intellectual connections with the works of philosophers such as Gadamer and Hadot, and social scientists like Elias and Goffman. Most important of all, however, was his late in-depth encounter with the work of Max Weber, in whom he recognized a kindred spirit and a selected predecessor.

Though this was not lost in some segments of the Foucault reception (Dreyfus and Rabinow, 1982; Gordon, 1991; Szakolczai, 1998), by then the damage had already been done. Foucault thus came to be regarded as a prime exponent of the very intellectual currents whose presuppositions he wanted to question and map in his work. In this, his fate can again be best compared to Max Weber's. As a result, in the burgeoning literature for or against Foucault, the problem he started to pose almost half a century ago concerning the taken for granted, allegedly universal but quite peculiar and questionable character of the way modern Western subjects form their subjectivity (selfhood or identity) – a problem very close to the Weberian interest in inner-worldly asceticism and in the methodical conduct of life, or the interest of Elias in the formation of habitus through the civilizing process – became blurred. This is demonstrated most paradoxically in the way the new literature on sexual or gender identities takes Foucault as one of its sources, although his work should rather be seen as a most effective way of problematizing this 'politics of identity.'

A number of important recent publication projects are rendering Foucault's work more accessible, in the French original as well as in English. Based on the 1994 Gallimard publication of all of Foucault published shorter writings (Foucault, 1994), Allen Lane published a three-volume selection in 1997–2001, edited by Paul Rabinow, Nikolas Rose, and James Faubion. Furthermore, and most importantly, the publication of Foucault Collège de France lectures is now well under way, both in French, edited by François Ewald and Alessandro Fontana, and in English, edited by Arnold Davidson and carefully translated by Graham Burchell. Starting in 1997, so far 9 of the 13 lecture courses delivered between 1970 and 1984 have been published in French, and 8 of these already appeared in English as well. Once this project is completed, and its contents carefully analyzed, the full significance of Foucault's work, and the paths opened up by him, will become fully visible.

While Foucault, just like Weber, is one of the most widely read social theorists of the past century, his work is similarly still more of an unfulfilled promise than a closed, exhausted chapter in the history of thought.

Fourier Analysis

Rainer Picard, Technische Universität Dresden, Dresden, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The core concepts of Fourier analysis and a variety of applications are briefly discussed (for simplicity mainly in the one-dimensional case). The connections to analyzing translation (or shift) invariant linear input–output systems, such as those described by differential-algebraic equations, ordinary differential equations, or partial differential equations and systems, are emphasized. The connection to various applications such as holography, image processing, visual perception, edge detection, motion analysis, and sampling is indicated.

What Is Fourier Analysis?

The term Fourier analysis commemorates the role that the French baron Jean-Baptiste-Joseph Fourier (21 March 1768 to 16 May 1830) played in utilizing methods involving a particular so-called integral transform, which now is known as the Fourier transform, to solve partial differential equations. Fourier's influential work has its precursors in early studies of the vibrating string by the Swiss mathematicians Daniel Bernoulli (8 February 1700 to 8 March 1782) and Leonhard Euler (15 April 1707 to 18 September 1783). We do not aim to give an introduction to Fourier analysis for the uninitiated, nor can we provide hands-on instruction on how to apply the concepts of Fourier analysis. There are fortunately numerous text books on various levels, which cover such needs (for a more accessible text, see, e.g., Howell, 2001). Here, in this rather brief exposition, we shall instead attempt to reveal the essence of why Fourier analysis is so powerful and of widespread usefulness. Since this may be – even to the practitioners of Fourier analysis – somewhat hidden, we shall need to elaborate on the central ideas in a little more detail.

Fourier analysis is the mathematical analysis of translation (or shift) invariant linear input–output systems, such as differential-algebraic equations, ordinary differential equations, or partial differential equations and systems arising thereof (unbeknownst to most) in the analysis of many if not the majority of real-world phenomena. Translation is a mathematical operation simply shifting the argument by a prescribed amount. For a given function f on the real line $\mathbb{R}$ the translation operation τ_h – translation of the argument by an amount $h\in\mathbb{R}$ – results in a new function $\tau_h f$, which is given by

$$(\tau_h f)(x) := f(x+h) \qquad [1]$$

for every $x\in\mathbb{R}$. (Here, '…∈…' should be read as '… element of… .' The colon marks the side of an equation that is defined by the other side; thus, the symbol ':=' could be read as 'defined as.') Shift invariance for an input–output system S means that applying a shift to the input results simply in the shifted output associated with the original input, that is, for every suitable function f on $\mathbb{R}$

$$S\tau_h f = \tau_h S f.$$

In other words, the input–output system S commutes with the shift τ_h. Such systems are well suited to be analyzed using the Fourier transform.

The Fourier Transformation

The Fourier transform can be described by its action on a suitable class of (in general) complex-valued functions f in terms of an integral (i denotes the imaginary unit):

$$\hat{f}(p) := \int_{-\infty}^{\infty} \exp(-2\pi \mathrm{i} p\gamma) f(\gamma)\mathrm{d}\gamma \quad \text{for every } p\in\mathbb{R}. \qquad [2]$$

A simple accessible class of functions would be piecewise continuous functions, i.e., functions that are continuous up to finitely many jumps, which in addition vanish outside of a bounded interval.

The mapping $\mathscr{F}$ suitably established via the association between the function f and the new function $\hat{f}$, i.e., $\hat{f} = \mathscr{F}f$, is called the Fourier transformation (see Goodman, 1968; Gaskill, 1978 as general references). The function $\hat{f}$ itself is referred to as the Fourier transform (or the spectrum) of f.

If f is real-valued it may often be convenient to consider the real part $\Re\hat{f}$ and the negative of the imaginary part $\Im\hat{f}$ of the Fourier transform $\hat{f}$ of f separately:

$$(\mathscr{F}_{\cos} f)(p) := \Re\hat{f}(p) = \int_{-\infty}^{\infty} \cos(2\pi p\gamma) f(\gamma)\mathrm{d}\gamma \text{ for every } p\in\mathbb{R}, \qquad [3]$$

$$(\mathscr{F}_{\sin} f)(p) := -\Im\hat{f}(p) = \int_{-\infty}^{\infty} \sin(2\pi p\gamma) f(\gamma)\mathrm{d}\gamma \text{ for every } p\in\mathbb{R}, \qquad [4]$$

which are known as the Fourier cosine transform and Fourier sine transform of f, respectively. By Euler's equation

$$\exp(2\pi \mathrm{i} x) = \cos(2\pi x) + \mathrm{i}\sin(2\pi x)$$

for every $x\in\mathbb{R}$, we see that

$$\mathscr{F} = \mathscr{F}_{\cos} - \mathrm{i}\mathscr{F}_{\sin}.$$

The operation of rescaling, which we define by

$$\sigma_L f := \sqrt{|L|} f(L\cdot), L\in\mathbb{R},$$

interacts with the Fourier transform in the following way:

$$\begin{aligned}\mathscr{F}(\sigma_L f) &= \sqrt{|L|}\mathscr{F}(f(L\cdot)) = \frac{1}{\sqrt{|L|}}(\mathscr{F}f)(\cdot/L)\\ &= \sigma_{1/L}(\mathscr{F}f) \text{ for } L\in\mathbb{R}, L\neq 0. \end{aligned} \qquad [5]$$

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43042-4

Clearly a smaller scale is turned into a larger scale and vice versa.

Using rescaling with -1, which is of course simply reflection at the origin, we get $\mathscr{F}^* := \sigma_{-1}\mathscr{F}$, which turns out to be the inverse of the Fourier transformation, appropriately called inverse Fourier transformation, and so we are led to the so-called Fourier inversion formula

$$f = \int_{-\infty}^{\infty} \exp(2\pi \mathrm{i} p\cdot)\hat{f}(p)\mathrm{d}p =: \mathscr{F}^*\hat{f}. \qquad [6]$$

Defining the norm of a suitable function f by

$$||f|| := \sqrt{\int_{-\infty}^{\infty} |f(s)|^2 ds},$$

it can be shown that $\mathscr{F}$ satisfies

$$||\mathscr{F}f|| = ||f||, \qquad [7]$$

i.e. $\mathscr{F}$ is norm-preserving, which in turn allows the extension of the Fourier transformation (as well as equations [6], [7], [5]) by continuity to all elements of a space denoted by $L^2(\mathbb{R})$. If in particular $||f|| = 1$ we say f is normalized. Such a norm provides a metaphorical concept of "length" or "size" for functions analogous to the absolute value for numbers. In this sense equality [7] states that the Fourier transform of f has the same "length" or "size" as f itself. The elements of $L^2(\mathbb{R})$ may be understood as being represented by certain square integrable functions and can be characterized by having piecewise continuous functions vanishing outside a bounded interval as approximations of every desired precision. This extension step generalizes the Fourier transformation to such functions, but the original integral expressions [2] and [6] do not in general make sense any more since square integrable functions need not be integrable. As a convenient structural trade-off for this inconvenience one finds, however, the remarkable benefit that every element $f \in L^2(\mathbb{R})$ is the Fourier transform of an element in $L^2(\mathbb{R})$ (given by $\mathscr{F}^*f$). In particular,

$$\mathscr{F}^*\mathscr{F}f = \mathscr{F}\mathscr{F}^*f = f \qquad [8]$$

for all $f \in L^2(\mathbb{R})$, i.e., we can recover f from $\hat{f} = \mathscr{F}f$ by simply applying $\mathscr{F}^*$ to $\hat{f}$. The rescaling operation σ_L introduced above has been defined to ensure that it shares this property with the Fourier transformation: $\sigma_L : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ is also norm-preserving and has $\sigma_{1/L} : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ as its (norm-preserving) inverse. Sometimes a rescaled version of $\mathscr{F}$ also goes by the name of Fourier transformation: $\sigma_{1/2\pi}\mathscr{F}$ with $\sigma_{1/2\pi}\mathscr{F}^*$ as its inverse. Indeed, we also have

$$\begin{aligned}\sigma_{1/2\pi}\mathscr{F}\left(\sigma_{1/2\pi}\mathscr{F}^*\right)f &= \mathscr{F}\mathscr{F}^*f = f = \mathscr{F}\mathscr{F}^*f \\ &= \sigma_{1/2\pi}\mathscr{F}^*\left(\sigma_{1/2\pi}\mathscr{F}\right)f\end{aligned}$$

for all $f \in L^2(\mathbb{R})$. In some application it is occasionally also found profitable to call $\sqrt{2\pi}\sigma_{1/2\pi}\mathscr{F}$ Fourier transformation with $\frac{1}{\sqrt{2\pi}}\sigma_{1/2\pi}\mathscr{F}^*$ as inverse. The reader should be aware of the possibility of these variants occurring. A variety of transformations derived by combination of various other norm-preserving transformations with the Fourier transformation are also of interest in this context. An example is the so-called Mellin transformation, which is scale invariant in contrast – as we have just seen – to the Fourier transformation itself. For image analysis (in polar coordinates) a radial Mellin transformation can be combined with a Fourier series expansion in the angular variable to produce the so-called Fourier-Mellin transformation, which shows advantages in analyzing scale and rotation motions of an image.

It follows from [7] that the inverse Fourier transformation $\mathscr{F}^*$ is also norm preserving. This norm, which makes $L^2(\mathbb{R})$ what is known a normed linear space, is induced by a so-called inner product given here by

$$\langle f|g\rangle := \int_{-\infty}^{\infty} \overline{f(x)}g(x)\mathrm{d}x$$

for $f, g \in L^2(\mathbb{R})$ (the bar denotes complex conjugation). Inner products allow the transfer of the geometric concept of orthogonality to other objects, here to $L^2(\mathbb{R})$: $f, g \in L^2(\mathbb{R})$ are called orthogonal if

$$\langle f|g\rangle = 0.$$

We note the following important relation between $\mathscr{F}$ and its inverse $\mathscr{F}^{-1} := \mathscr{F}^*$:

$$\langle \mathscr{F}f|g\rangle = \langle f|\mathscr{F}^*g\rangle \qquad [9]$$

for all $f, g \in L^2(\mathbb{R})$. Relation [8] shows that by transforming with $\mathscr{F}$ no information is lost. In particular, orthogonality and normalization are preserved. This information is, however, encoded in such a form that local information in $\hat{f}$ represents global information in the original f. This feature is utilized (for the two-dimensional case, see the brief discussion in section Higher dimensional Fourier transformation) in image processing where local information is removed from or added to the Fourier transform $\hat{f}$ of an image f (modeled as an illumination distribution function f) to actually improve the global visual appearance of the original f by, for example, removing grid structures or sharpening edges. The visual system itself appears to perform image processing, at least approximately, in this manner (see Cornsweet et al., 1984; Georgeson, 1979; Graham, 1981). Another application of the Fourier transformation can be found in holography (see Stroke, 1969). Holographic encoding has been utilized as a model for particular features in memory and perception (Pribram et al., 1974). The stability of the original data f despite 'noise' affecting the Fourier transformed signal $\hat{f}$ is also utilized in data transmission security.

In applications one has to deal with real quantities (the complex notation just being a matter of mathematical convenience). In this context, the so-called power spectrum $|\hat{f}(\cdot)|^2$ is of particular interest (the inverse Fourier transform of the power spectrum is known as the autocorrelation function). The power spectrum is usually the only part of the Fourier spectrum $\hat{f}$ that can actually be measured in experiments. The power spectrum (usually in its two-dimensional form, see later) is utilized to distinguish so-called Fourier motion from non-Fourier motion in the analysis of moving images (Chubb and Sperling, 1988; Fleet and Langley, 1995).

Note that if f is even, i.e., $f(-x) = f(x)$, then $\mathscr{F}f = \mathscr{F}_{\cos}f$ (the Fourier cosine transform), and if f is odd, i.e., $f(-x) = -f(x)$, then $\mathrm{i}\,\mathscr{F}f = \mathscr{F}_{\sin}f$ (the Fourier sine transform) all of which are then real quantities if f is real-valued. Even for the complex-valued case, the Fourier cosine transformation would recover the even part $E(f)(x) := \dfrac{f(x)+f(-x)}{2}$ of f from $\hat{f}$ and the Fourier sine transformation its odd part $O(f)(x) := \dfrac{f(x)-f(-x)}{2}$. Readers who are uncomfortable with complex numbers (the less mathematically inclined reader may also find in Weisstein (1980) an interesting and entertaining survey on Fourier transforms) may restrict their attention to odd and even real functions separately. The information contained in a real even or odd function is then fully preserved by its (real) Fourier cosine and its (real) Fourier sine transform, respectively.

To give a flavor of how the Fourier transformation acts, we introduce two interesting examples (for a more visual approach to Fourier transforms consult Harburn et al. (1975)). The Gauss distribution function γ – well-known from statistics – is given by $\gamma(x) := \exp(-\pi x^2)$ for $x \in \mathbb{R}$. It has the remarkable property that

$$\mathscr{F}_{\cos}\gamma = \mathscr{F}\gamma = \gamma. \qquad [10]$$

For the second example, we introduce the notation χ_M for the characteristic function of a subset $M \subseteq \mathbb{R}$ defined by

$$\chi_M(x) := \begin{cases} 1 & \text{for} \quad x \in M, \\ 0 & \text{for} \quad x \notin M, \end{cases}$$

for $x \in \mathbb{R}$. The characteristic function $\Pi := \chi_{[-1/2,1/2]}$ of the unit interval $[-1/2,1/2]$ (box function) has the so-called sinc function as Fourier transform:

$$\mathscr{F}_{\cos}\Pi = \mathscr{F}\Pi = \mathrm{sinc},$$

where $\mathrm{sinc}(x)$ is defined for all real x by

$$\mathrm{sinc}(x) := \begin{cases} \dfrac{\sin(\pi x)}{\pi x} & \text{for} \quad x \neq 0, \\ 1 & \text{for} \quad x = 0. \end{cases}$$

The sinc function is important in connection with the Shannon sampling theorem (see below).

The Fourier Transformation as a Spectral Representation

Derivatives

The significance of representing a function in terms of its Fourier transform becomes clear if we consider how that transform interacts with differentiation, symbolized by ∂:

$$\partial f = f'.$$

We find that

$$\partial = \mathscr{F}^{-1} 2\pi\mathrm{i}m\mathscr{F} \ \text{ in } \ L^2(\mathbb{R}), \qquad [11]$$

where m stands for the multiplication-by-argument operation, i.e.,

$$(mf)(p) := pf(p) \text{ for all } f \in L^2(\mathbb{R}),\ p \in \mathbb{R}.$$

It should be noted that defining the differential operator ∂ by the right-hand side of [11] implies a generalized concept of differentiability.

The elements in the domain of definition $\{f \in L^2(\mathbb{R}) | m\hat{f} \in L^2(\mathbb{R})\}$ of m as an operator in $L^2(\mathbb{R})$ are continuous functions but need not be differentiable in the classical sense. Equation [11] – called a spectral representation for $\dfrac{1}{2\pi\mathrm{i}}\partial$ – shows the equivalence of applying $\dfrac{1}{2\pi\mathrm{i}}\partial$ with multiplication-by-argument m or in other words of differentiation ∂ with multiplication by $2\pi\mathrm{i}m$. The obvious symmetry of m, i.e.,

$$\langle mf|g\rangle = \langle f|mg\rangle \text{ in } L^2(\mathbb{R}) \qquad [12]$$

implies, via the spectral representation of $\dfrac{1}{2\pi\mathrm{i}}\partial$, the skew symmetry of ∂, i.e.,

$$\langle \partial f|g\rangle + \langle f|\partial g\rangle = 0 \text{ in } L^2(\mathbb{R}), \qquad [13]$$

known as integration by parts.

Functions of ∂

The Fourier transform spectral representation in [11] generalizes to polynomials in ∂ and $2\pi\mathrm{i}m$. That is, for any polynomial P we have

$$P(\partial) = \mathscr{F}^{-1}P(2\pi\mathrm{i}m)\mathscr{F}.$$

This suggests that we define more general functions of ∂ by letting

$$F(\partial) := \mathscr{F}^{-1}F(2\pi\mathrm{i}m)\mathscr{F} \text{ in } L^2(\mathbb{R}), \qquad [14]$$

where F can be fairly general (and even matrix-valued, in which case the Fourier transformation is to be carried out component-wise). This concept is extremely powerful, since a large class of models discussed in so-called linear systems theory, (see Gaskill, 1978; Norman, 1981), can be understood as such functions $F(\partial)$ acting on an input u resulting in an output $F(\partial)u$. Characterizing properties of such systems are that their input–output relations are linear and translation-invariant, i.e., sums, multiples, and shifts of input result in sums, in (up to scaling) the same multiple and equally shifted output. Indeed, translation τ_h defined in [1] is itself a function of ∂ in the above sense:

$$\tau_h = \exp(h\partial) = \mathscr{F}^{-1}\exp(2\pi\mathrm{i}hm)\mathscr{F}.$$

It may be interesting to note that by substituting the series expansion for the exponential function, this formula (if applied to suitable functions) is easily recognized as nothing but the Taylor expansion. Translation-invariant, linear systems occur (usually in a higher dimensional form, compare section Higher Dimensional Fourier Transform) as good approximations of many aspects of visual and auditory perception.

Convolution

The action of a function $\hat{S}\left(\dfrac{1}{2\pi\mathrm{i}}\partial\right)$, where $\hat{S}$ denotes the Fourier transform of S, defines what is called a convolution (of S with g):

$$S * g := \hat{S}\left(\frac{1}{2\pi\mathrm{i}}\partial\right)g, \qquad [15]$$

which is defined for any g in the domain of $\hat{S}\left(\frac{1}{2\pi i}\partial\right)$. In many cases, $S * g$ is actually given as an integral expression, which is a so-called convolution integral:

$$(S * g)(x) = \int_{-\infty}^{\infty} S(x-y)g(y)\mathrm{d}y \text{ for } x \in \mathbb{R}. \qquad [16]$$

In accordance with [15] for such convolution integrals, the so-called convolution theorem holds

$$\mathscr{F}(S * g) = \hat{S}(m)\hat{g} = \hat{S}\hat{g}. \qquad [17]$$

Particularly, the above-mentioned relationship between the autocorrelation and the power spectrum reveals that the autocorrelation is a convolution.

Generalized Fourier Transformation and Some Applications

We extend the meaning of $\langle\cdot|\cdot\rangle$ by introducing even more generalized functions f (also called distributions) as linear functionals:

$$\langle f|\varphi\rangle := f(\varphi),$$

where φ is a smooth function, i.e., infinitely often differentiable, vanishing outside a bounded interval in $\mathbb{R}$ – we shall write $\varphi \in C_0^\infty(\mathbb{R})$ – such that f is linear, i.e.,

$$\langle f|\varphi + \alpha\psi\rangle = \langle f|\varphi\rangle + \alpha\langle f|\psi\rangle$$

for all complex numbers α and all $\varphi, \psi \in C_0^\infty(\mathbb{R})$. Clearly, for any $f \in L^2(\mathbb{R})$ the inner product $\langle f|\varphi\rangle$ defines a generalized function (i.e., a complex-valued linear function defined for $\varphi \in C_0^\infty(\mathbb{R})$), but $\exp(2\pi i p\cdot)$, although not an element of $L^2(\mathbb{R})$, also defines a generalized function via

$$\begin{aligned}\langle \exp(2\pi i p\cdot)|\varphi\rangle &:= \int_{\mathbb{R}} \overline{\exp(2\pi i p x)}\varphi(x)\,\mathrm{d}x \\ &= \hat{\varphi}(p)\end{aligned} \qquad [18]$$

for all $\varphi \in C_0^\infty(\mathbb{R})$. Further, a generalized function, which is not given by a classical function at all, is the distribution $\delta_{\{\omega\}}$ defined by

$$\delta_{\{\omega\}}(\varphi) = \langle \delta_{\{\omega\}}|\varphi\rangle := \varphi(\omega) \text{ for all } \varphi \in C_0^\infty(\mathbb{R}).$$

(This distribution samples evaluate the 'test function' φ at point $\omega \in \mathbb{R}$.) The special choice $\delta := \delta_{\{0\}}$ is the so-called Dirac-δ-distribution. Since it can only be distinguished from 0 by testing with $\varphi \in C_0^\infty(\mathbb{R})$ satisfying $\varphi(0) \neq 0$ we say $\delta = 0$ on $\mathbb{R} \setminus \{0\}$. However, δ is (by definition) not identically zero as a functional. It is particularly useful in many contexts to have $\delta_{\{\omega\}}(=\tau_{-\omega}\delta)$ as a mathematical model for a physical phenomenon that is vanishingly small in space or time such as a mass point, an elementary charge, a light point, a short impulse, or a molecule at location ω (see section Higher Dimensional Fourier Transform for the particularly interesting higher dimensional case).

With sufficient care, a large class of such distributions f (e.g., the so-called tempered distributions) can be established for which the concept of derivative, multiplication by the argument, and Fourier transform can (guided by [9] and [13]) be generalized by defining

$$\begin{aligned}\langle \partial f|\varphi\rangle &:= -\langle f|\partial\varphi\rangle, \\ \langle \mathscr{F}f|\varphi\rangle &:= \langle f|\mathscr{F}^*\varphi\rangle, \\ \langle \mathscr{F}^*f|\varphi\rangle &:= \langle f|\mathscr{F}\varphi\rangle,\end{aligned} \qquad [19]$$

for all $\varphi \in C_0^\infty(\mathbb{R})$. As an example for this generalized differentiation, we find for the characteristic function $\chi_{]0,\infty[}$ of the interval $]0, \infty[$ of all positive real numbers

$$\partial\chi_{]0,\infty[} = \delta.$$

The Fourier transform of the distribution $\delta_{\{\omega\}}$ is, according to [18] and [19],

$$\mathscr{F}\delta_{\{\omega\}} = \exp(-2\pi i\omega\cdot) \qquad [20]$$

and conversely we have

$$\mathscr{F}\exp(2\pi i\omega\cdot) = \delta_{\{\omega\}}. \qquad [21]$$

The latter fact can be used to detect oscillatory behavior of frequency ω, which may be hiding in seemingly random data. The oscillation would show up in the Fourier transformed data as a 'peak' or 'spike' at point ω.

The concept of functions of ∂ and in particular the concept of convolution can also be carried over to tempered distributions. This will be illustrated by a few applications.

Impulse Response

The importance of the Dirac-δ-distribution is that a translation-invariant, linear system $S(\partial)$ is completely described by its impulse response $S(\partial)\delta$. Indeed, the general response $S(\partial)f$ is given by convolution with the impulse response

$$S(\partial)F = (S(\partial)\delta) * F$$

In the case that $S(\partial)$ is the solution operator $S(\partial) = P(\partial)^{-1}$ of the differential equation $P(\partial)u = f$, P a polynomial, the impulse response is also known as fundamental solution (or Green's function).

Shannon's Sampling Theorem

Another distribution of particular interest is the (sampling or) comb distribution $Ш := \sum_{n=-\infty}^{+\infty} \delta_{\{n\}}$, which takes samples at every integer point. This distribution is reproduced by the Fourier transformation, i.e.,

$$\mathscr{F}Ш = Ш, \qquad [22]$$

which is another way of stating the Poisson summation formula:

$$\mathscr{F}\sum_{n=-\infty}^{+\infty} \delta_{\{n\}} = \sum_{n=-\infty}^{+\infty} \exp(-2\pi i n\cdot) = \sum_{n=-\infty}^{+\infty} \delta_{\{n\}}.$$

Note that for the first equality we have used [18] and [20].

If $f \in L^2(\mathbb{R})$ and $f = 0$ outside of $[-1/2, 1/2]$, then $Ш * f$ is simply the periodic extension of f from the unit interval $[-1/2, 1/2]$, to all of $\mathbb{R}$. Therefore, by 'cutting off' with the characteristic function $\Pi := \chi_{[-1/2,1/2]}$ we recover

$$f = \Pi(Ш * f). \qquad [23]$$

As we now demonstrate, the so-called Shannon sampling theorem follows from [22]. In fact, applying [23] to $\hat{f} \in L^2(\mathbb{R})$ with $\hat{f} = 0$ outside of $[-1/2, 1/2]$ we get

after the inverse Fourier transformation has been applied that

$$\begin{aligned} f &= F^*(\Pi(\text{Ш} * \hat{f})) \\ &= \text{sinc} * \left(\sum_{n=-\infty}^{+\infty} f(n)\delta_{\{n\}} \right), \\ &= \sum_{n=-\infty}^{+\infty} f(n)\text{sinc}(\cdot - n), \end{aligned} \qquad [24]$$

which is indeed the statement of Shannon's sampling theorem.

Any function f with $\hat{f}$ vanishing outside a bounded interval is called band-limited. Since any such function can be easily rescaled to have $\hat{f} = 0$ outside of $[-1/2,1/2]$, [24] shows that any band-limited function f can be completely recovered from equidistant sampling. The sampling theorem has many applications, in particular in the analysis of auditory and visual perception (see, e.g., Yellot, 1990).

By interchanging the role of f and $\hat{f}$ in the Shannon sampling theorem we have

$$\hat{f} = \text{sinc} * \left(\sum_{n=-\infty}^{+\infty} \hat{f}(n)\delta_{\{n\}} \right) \qquad [25]$$

and after applying the inverse Fourier transformation we obtain the so-called Fourier series

$$f = \sum_{n=-\infty}^{+\infty} \hat{f}(n)\Pi\exp(2\pi\text{i}n\cdot) \qquad [26]$$

of a function $f \in L^2(\mathbb{R})$ with $f = 0$ outside of $[-1/2,1/2]$. Note that $\{\Pi\exp(2\pi\text{i}n\cdot) | n \in \mathbb{Z}\}$ is an orthonormal set, i.e., all elements are normalized and pairwise orthogonal, which allows a Fourier series expansion in the sense of [26] for every $f \in L^2(\mathbb{R})$ with $f = 0$ outside of $[-1/2,1/2]$.

Wavelets

It is interesting to note that the set of functions $\{\tau_{-n}\text{sinc} | n \in \mathbb{Z}\}$ occurring in Shannon's sampling theorem is also an orthonormal set in $L^2(\mathbb{R})$. Indeed, this is a complete orthonormal set in $L^2(\mathbb{R})$ in the sense that every $f \in L^2(\mathbb{R})$ has a series expansion with respect to these functions. By virtue of this we get

$$g = \sum_{n=-\infty}^{+\infty} \langle \tau_{-n}\text{sinc} | g \rangle \tau_{-n}\text{sinc}$$

for every $g \in L^2(\mathbb{R})$. According to [24] we have that for functions with bandwidth less than or equal to 1, i.e., with $\hat{f} \in L^2(\mathbb{R})$ such that $\hat{f} = 0$ outside of $[-1/2,1/2]$, g is actually represented by this sum. In particular,

$$\langle \tau_{-n}\text{sinc} | g \rangle = g(n)$$

for $n \in \mathbb{Z}$. To cover all band-limited functions one would have to allow for sufficiently large scaling factors L. Letting, e.g., $L = 2^p, p \in \mathbb{Z}$, then $(\sigma_{2^p}(\tau_{-n}\text{sinc}))_{p,n\in\mathbb{Z}}$ can be used to approximate any element $f \in L^2(\mathbb{R})$. All elements of $(\sigma_{2^p}\tau_{-n}\text{sinc})_{p,n\in\mathbb{Z}}$ are generated by the combination $\sigma_{2^p}\tau_{-n}$ of scaling and translation from the single function sinc, the so-called scaling function of this particular construction. Unfortunately, $(\sigma_{2^p}\tau_{-n}\text{sinc})_{n\in\mathbb{Z}}$ is only orthonormal for fixed $p \in \mathbb{Z}$. By a suitable orthonormalization procedure (multiresolution analysis) one can obtain, however, that $(\sigma_{2^p}\tau_{-n}(\text{sinc} - \sqrt{2}\sigma_2(\text{sinc})))_{p,n\in\mathbb{Z}}$ is a complete orthonormal system in $L^2(\mathbb{R})$. Any orthonormal system generated by $\sigma_{2^p}\tau_{-n}, p, n \in \mathbb{Z}$, from a so-called mother wavelet – here the function $(1 - \sqrt{2}\sigma_2)\text{sinc}$ – is called an orthonormal wavelet basis. Wavelets derive their utility largely from the fact that they do not have a fixed base scale like, e.g., the Fourier system $(\exp(2\pi\text{i}n\cdot)\Pi)_{n\in\mathbb{Z}}$, which by allowing for translations would also yield an orthonormal system $(\tau_r(\exp(2\pi\text{i}n\cdot)\Pi))_{n,r\in\mathbb{Z}}$ for $L^2(\mathbb{R})$. Wavelets naturally allow for the 'right' scale in $L = 2^p, p \in \mathbb{Z}$, to emerge for any given f according to their weight in its orthonormal expansion. As the Fourier transform may be considered to be a continuously scaled Fourier series, there are also continuously scaled versions of wavelet expansions known as wavelet transforms.

Higher Dimensional Fourier Transformation

Much of what has been explored above can be generalized to higher dimensions. This is due to the particular product structure of the higher dimensional exponential

$$\begin{aligned} &\exp(2\pi\text{i}(x_1p_1 + x_2p_2 + \ldots + x_np_n)) \\ &\quad = \exp(2\pi\text{i}x_1p_1)\exp(2\pi\text{i}x_2p_2)\ldots\exp(2\pi\text{i}x_np_n) \end{aligned}$$

for $x_i, p_i \in \mathbb{R}$, $i = 1, 2, \ldots, n$, i.e., $(x_1, x_2, \ldots, x_n), (p_1, p_2, \ldots, p_n) \in \mathbb{R}^n$. Thus, the n-dimensional Fourier transformation, $n \in \mathbb{N}, n \geq 2$, can be understood as a repeated one-dimensional Fourier transform, i.e.,

$$\begin{aligned} (\mathscr{F}f)(p) &= \int_{\mathbb{R}^n} \exp(-2\pi\text{i}xp)f(x)\text{d}x \\ &= \int_{-\infty}^{\infty} \exp(-2\pi\text{i}x_1p_1) \int_{-\infty}^{\infty} \exp(-2\pi\text{i}x_2p_2) \\ &\quad \ldots \int_{-\infty}^{\infty} \exp(-2\pi\text{i}x_np_n)f(x)\,\text{d}x_n \ldots \text{d}x_2\,\text{d}x_1, \end{aligned}$$

where $x = (x_1, x_2, \ldots, x_n)$, $p = (p_1, p_2, \ldots, p_n)$, and $xp = \sum_{i=1}^n x_ip_i$. As a consequence, many of the above considerations can be carried over to the higher dimensional case. For example, with $x^2 := xx$, $x \in \mathbb{R}^n$, the definition of the Gauss distribution function carries over to the n-dimensional case and the property of [10] remains true. The n-dimensional Dirac-δ-distribution $\delta = \delta_{\{0\}}$ simply takes a single sample at 0 and the shifted version $\delta_{\{x\}}$ correspondingly at $x \in \mathbb{R}^n$. The latter still has $\exp(-2\pi\text{i}x\cdot)$ as its Fourier transform. In addition, $\text{Ш} := \sum_{x\in\mathbb{Z}^n} \delta_{\{x\}}$, which takes samples at every point of $\mathbb{R}^n$ with integer coordinates, still satisfies

$$\mathscr{F}\text{Ш} = \text{Ш}. \qquad [27]$$

Thus, in particular, corresponding variants of the Shannon sampling theorem and of the Fourier series expansion hold. Note, however, that the scaling has to be generalized to $\sigma_L f := |L|^{n/2} f(L\cdot)$, but then [5] also carries over to the n-dimensional case. The higher dimensional Fourier transformation finds its applications in higher dimensional, translation-invariant, linear systems (Norman, 1981). A particularly prominent application is in optics (see, e.g., Gaskill, 1978; Goodman, 1968; Taylor, 1978). As pointed out earlier, the visual

system may be considered at least approximately to be a two-dimensional (or three-dimensional) example of such a system and may be analyzed with Fourier techniques (see, e.g., Cornsweet et al., 1984; Georgeson, 1979; Graham, 1981; Julesz, 1980; Yellot, 1990). Higher dimensional Fourier methods also play a central role in the discussion and analysis of problems associated with the perception of moving images. For a survey of recent developments see Burr and Thompson (2011).

Abstract

The Institute for Social Research, or Frankfurt School, is an interdisciplinary research center associated with the University of Frankfurt in Germany and responsible for the founding and various trajectories of Critical Theory in the contemporary humanities and social sciences. Three generations of critical theorists have emerged from the Institute. The first generation was most prominently represented in the twentieth century by Max Horkheimer, Herbert Marcuse, Theodor W. Adorno, Walter Benjamin, Leo Löwenthal, and also for some time Erich Fromm. The so-called 'second generation' of the Institute is centrally represented by Jürgen Habermas, whose work has functioned as the focal point of a wide range of critical theorists. The third generation of the Frankfurt School is represented by Axel Honneth who emerged as a new center, with different strands or readings of who else belongs to the third generation, some in Germany, some internationally, and some more in sociology and social and political theory than philosophy.

Introduction

The Institute for Social Research (*Institut für Sozialforschung*), an academic institution of the University of Frankfurt in Germany opened in 1924 and commonly referred to as the Frankfurt School, comprises a group of scholars who promote a critical theory of society, or simply critical theory, and approach its study from interdisciplinary and multidisciplinary perspectives. The critical theorists who made up the first generation of the Frankfurt School include social philosopher Max Horkheimer (1895–1973), philosopher and political theorist Herbert Marcuse (1898–1979), social psychologist and psychoanalyst Erich Fromm (1900–80), philosopher, sociologist, and musicologist Theodor W. Adorno (1903–69), social scientist and philosopher Friedrich Pollock (1894–1970), sociologist Leo Löwenthal (1900–93), as well as political and legal theorist Otto Kirchheimer (1905–65) and political theorist Franz Neumann (1900–54). These scholars shared a common Jewish ancestry and a Marxist political and scholarly orientation. Cultural theorist and literary critic Walter Benjamin (1892–1940) was a loose affiliate of the Institute in its first generation, as were cultural critic and sociologist Siegfried Kracauer (1889–1996) and philosopher Ernst Bloch (1885–1977). Other lesser known full-members of the Institute in its first generation included historian Karl August Wittfogel (1896–1988) and economist and historian Henryk Grossman (1881–1950). The so-called second generation of the Frankfurt School is most prominently represented by philosopher and sociologist Jürgen Habermas (1929–present), whose work, however, has been flanked and aided by Albrecht Wellmer (1933–present) and Claus Offe (1940–present). The third generation is represented by the social philosopher Axel Honneth (1949–present) at the center, the latter of whom is currently director of the Institute. There exist different strands or readings of who else belongs to the third generation, some in Germany, some internationally, some more in sociology and social theory. Marking the internationalizing of Critical Theory, social philosophers Nancy Fraser (1947–present) and Seyla Benhabib (1950–present) are in some readings considered representatives of the third generation of the Frankfurt School. Other readings regard the work of political theorist Claus Offe and philosopher and social theorist Oskar Negt (1934–present) as representative of the third generation, while others also consider the work of social theorist Hans Joas (1948–present) as representative of this generation.

The Institute was founded on an endowment made possible by Felix Weil (1898–1975), an Argentinean-born German Marxist scholar and son of a millionaire businessman. Philosopher Carl Grünberg (1861–1940) was the Institute's first director. In October 1930, Max Horkheimer succeeded Grünberg as the Institute's director. In 1934, the Institute relocated to the United States, finding a home at Columbia University in New York City, where it stayed until 1950, at which time it was then moved back to the University of Frankfurt in Germany.

History of the Frankfurt School I: From 1923 to 1969

Historical Background and Institutional Beginnings

The Institute for Social Research opened in 1924, founded on money given from Felix Weil, an Argentinean-born German Marxist scholar and son of a millionaire businessman. Sociologist Kurt Albert Gerlach (1886–1922), a left-wing socialist professor, was an important figure throughout the creation process, despite dying before the Institute's founding. Weil intended to found an Institute that served first and foremost for the study and broadening of scientific Marxism. Weil, with Gerlach's assistance, created an institute connected to the University of Frankfurt but independent from it in that is was directly answerable to the Prussian Ministry of Culture. Weil and his father financed the building and equipment of the Institute, paid it a yearly grant of 120 000 marks, and offered the lower floor to the university's Faculty of Economics and Social Science, in addition to later on funding the professorial chair which the Institute's director held in that faculty. Authorization from the ministry for the foundation of an Institute for Social Research as an academic institution of the University of Frankfurt which will also serve the University for

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61221-7

teaching purposes' came through at the beginning of 1923. Construction began in March of that year. Marxist philosopher Carl Grünberg became the Institute's first director in 1924. In Grünberg, Weil had found a director of the new Institute who was both a full Marxist and a recognized scholar. The Faculty of Economics and Social Sciences in Frankfurt agreed to Grünberg as director at once and voted unanimously at the beginning of January 1923 to nominate him to the ministry for appointment to the professorial chair funded by the Institute for Social Research. On Sunday, 22 June 1924, at 11 a.m., the academic ceremony celebrating the opening of the Institute for Social Research was held in the hall of the University of Frankfurt.

Grünberg's first two assistants were social scientist and philosopher Friedrich Pollock and economist and historian Henryk Grossman. Pollock had taken his doctorate in Economics at the University of Frankfurt in 1923, and had temporarily been director of the Institute until Grünberg arrived. Grünberg offered him a position as a research associate at the Institute, and he accepted it immediately. Grossman joined the Institute in 1926 at Grünberg's invitation, also as a research associate. Another of the Institute's very first assistants was Rose Wittfogel, who was a librarian. In 1925, her husband, historian Karl August Wittfogel, became a full-time research associate of the Institute. Sociologist Leo Löwenthal started receiving a scholarship from the Institute in 1926.

The Turn toward a 'Critical Theory of Society'

The decisive turn for the Institute for Social research came when Max Horkheimer assumed the position of its second director. In January 1928, Grünberg had to stop work and resign as director of the Institute due to a stroke. There was an interim period when Pollock served as acting director. In October 1930, Pollock (who had been Weil's executive agent since 1925), representing the board of the Institute of Social Research, and social philosopher Max Horkheimer, who had been appointed 2 months before by the Faculty of Philosophy at the University of Frankfurt to Professor of Social Philosophy, signed a contract making Horkheimer the Institute's new director. On 24 January 1931, Horkheimer gave his inaugural lecture on taking up the Chair of Social Philosophy and the directorship of the Institute for Social Research. Horkheimer launched a new research program which intended to overcome the crisis of Marxism by fusing social philosophy and empirical social science. Horkheimer proved a highly integrative and formidable research organizer, who understood to be highly influential less by fully defined ideas and theories and more by suggesting the broad outlines within which inter- and multidisciplinary work of original scholars could unfold. The perspective which he developed in the early writings of the Institute, including his inaugural address, was enabling rather than constraining, gave direction without determining every detail.

In a nutshell, the first and founding generation of the Frankfurt School attempted to actualize Marx's critique of capitalism. This project not only involved the need to account for capitalism's continued existence, but also for the rise of fascist as well as state-capitalist systems of totalitarian domination. Marx's critique thus needed to be expanded to explain the susceptibility of the masses, including the working class, to nationalist propaganda, the fascist cult of leadership, or the (equally disabling) complacency with the existing order of injustice via consumerism and the culture industry. The approach, as we saw, was to combine Marx's analysis of economic macrostructures with a Freudian social psychology such that the lack of revolutionary agency could be explained: Capitalism, so their argument, undermines the familial structures necessary for autonomous agency, and thereby opens the door for cultural-political formations such as fascism and consumerism. Here the subject identifies with surrogate pleasures, its own inability to change anything, or the submission under a strong leader who falsely represents one's own fake powers. The subtlety and comprehensiveness with which this research program was played out in all possible domains of social and cultural experience still today looks for an equal. From Horkheimer's, Adorno's and Marcuse's critique of ideology in philosophy; Adorno's, Löwenthal's and Benjamin's analysis of music, literature, and film; Pollock's and Kirchheimer's analysis of the economy and the state; as well as numerous other studies; the reconstruction of how economic and political powers shape agents such that the normative overcoming of an unjust social order remains impossible still today defines a practically unmatched standard for the fusion of empirical social research and philosophical conceptualization.

The Historical Unfolding of a Collaborative Social Theory

The Institute began a new era with Horkheimer and with his new journal *Zeitschrift für Sozialforschung* (Journal for Social Research), launched in 1932, as its public face. An important collaborator from the beginning of the Institute's Journal for Social Research was philosopher, sociologist, and musicologist Theodor W. Adorno. The first issue of the Institute's *Zeitschrift für Socialforschung* included contributions by Erich Fromm and Leo Löwenthal. Löwenthal had initial discussions with philosopher and political theorist Herbert Marcuse in Frankfurt in 1932, which led to his admission to the Institute in 1933. Thus Horkheimer's assistants at the Institute included Fromm, Pollock, Löwenthal, Adorno, and Marcuse. Looser connections were also established to scholars who at a later time would become more closely tied to the Institute, including political theorist Franz Neumann and political and legal theorist Otto Kirchheimer (1905–65).

By the beginning of 1933, the Institute and its members offered competence in a number of scholarly areas, with Marcuse and Horkheimer representative of the Institute's strength in philosophy, Fromm and Löwenthal covering psychology, Pollock, Karl August Wittfogel, and Grossman showing expertise in economy and economic history, Marcuse and Löwenthal in aesthetics and literature, and Grossman in statistics. From the winter semester of 1930–31 onwards, psychoanalyst and social psychologist Erich Fromm was listed as a member of the Institute's teaching staff, alongside Horkheimer, Grossman, and Pollock.

When Hitler became Chancellor in January that year, Horkheimer was ready with plans for a move from Germany. Pollock and Wittfogel were safe in Switzerland at the time, and the Institute's other members were soon able to leave Germany as well. Horkheimer had pondered the idea of relocating the Institute to another location in Europe, and branches had

already been established in Switzerland, Holland, and France. Horkheimer soon realized the only feasible alternative for relocation of the Institute would be to the United States. The Institute was offered an office building in New York City, and was given a contract that loosely tied them to Columbia University there. Therefore the Institute relocated to the United States in 1934, with their new home at Columbia University, where it would eventually stayed until 1950, at which time it was relocated back to the University of Frankfurt in Germany. After the initial relocation to the United States, the Institute's work slowly resumed there by the summer of 1934. By the autumn of that same year, nearly all of the Institute's scholars were reunited in the United States. However, Adorno stayed a bit longer in Germany and did not join the Institute in the United States until 1938. When the Institute first relocated to New York in 1934, Adorno went to Oxford University in England, where he unsuccessfully studied philosophy under the British analytic philosopher Gilbert Ryle (1900–76).

During its first years in the United States, the Institute worked on projects that had been initiated in Germany. Among the most important of these was an empirical social psychology project in which material had been collected before the Institute's relocation. The result of this project was published as *Studien über Autorität und Familie*. It represented the first, but unfortunately also the last, large-scale empirical study of the Institute displaying the original aims and scientific visions of Horkheimer's group of scholars. A forerunner to the study was almost completed by Fromm but never published. This fact, coupled with other internal difficulties of the Institute, led to the Institute's parting ways with Fromm in 1939. Fromm's importance at the Institute had been on the increase since the early 1930s. His social-philosophical interpretation of Freudian psychoanalysis, paired with Horkheimer's high regards for social-psychological explanations was integral for the *Studien*. Since the beginning of Horkheimer's reign, psychoanalysis had been a central method in the dialectical materialism of the Frankfurt School. In addition to Fromm's psychoanalysis and social psychology, Otto Kirchheimer pursed a path-breaking study in criminology while a member of the Institute in the 1930s. His coauthored study in criminology was titled *Punishment and Social Structure* (1939). The study became known as an early example of scholarship in the field of critical criminology.

Fromm eventually decided to stay permanently in the United States, becoming a major name in social psychology and psychoanalysis. Marcuse and Löwenthal also decided to stay in the United States after the Institute had relocated back to Frankfurt in 1950 with Marcuse, who taught at UC San Diego, becoming a major figure of the American New Left in the 1960s, and Löwenthal assuming a sociology professorship at UC Berkeley.

The Philosophical Turn and the Dialectic of Enlightenment

Horkheimer and Adorno coauthored *Dialectic of Enlightenment* in 1944 during their stay in Los Angeles, California. Horkheimer and Adorno lived in the Pacific Palisades neighborhood of Los Angeles, among a group of notable émigré intellectuals and artists who had fled Europe in the rise of National Socialism, including Thomas Mann (1875–1955), Bertold Brecht (1898–1956), and Arnold Schoenberg (1874–1951). *Dialectic of Enlightenment* became the most well known of the works in social philosophy from the Frankfurt School. While it certainly was, in some way, an immediate continuation of the problems discussed by earlier essays from the 1941 issue of the Institute's *Zeitschrift*, it was nevertheless also a complete redefinition of the project. In *Dialectic of Enlightenment*, a broad theoretical framework develops the decline, or rather the complete reversal, of Enlightenment reason. It is true, there was also a more specialized discussion of phenomena such as the 'Culture Industry' and anti-Semitism, and so a certain connection to the meta-theoretical framework and thus a continuation of the interdisciplinary vision from the earlier versions of the Institute's critical theory was still present. The *Dialectic of Enlightenment* was, in fact, a philosophical work, but the critical methodologies employed by Horkheimer and Adorno throughout the book ultimately made it multidisciplinary, and therefore still a valid example of the Institute's critical theory. *Dialectic of Enlightenment* was an exemplar of the Institute's project of interdisciplinary and multidisciplinary research to the extent that it entailed the discussion of philosophy, myth, enlightenment, morality (including the work of philosopher Marquis de Sade), anti-Semitism, and the Culture Industry. However, the overall context of these discussions was now a pessimistic account of the history of enlightened reason. The *Dialectic of Enlightenment* is ultimately a philosophical text that reconstructs, in the methodology of philosophy of history, how reason turned into its opposite. In such fashion, Critical Theory of this magnitude has become a negative philosophy of history.

Adorno's Rise and the Frankfurt School's Rise to Public Prominence

Adorno had continued to pursue multidisciplinary research in the United States after the publication of *Dialectic of Enlightenment*. His *Philosophy of New Music* was published in 1949, and he also focused on the sociology of music in that time period. He collaborated with Daniel J. Levinson, Max Horkheimer, and Else Frenkel-Brunswik in the writing of *The Authoritarian Personality* (1950). Adorno had collaborated with sociologist Paul Lazarsfeld (1901–76) in the Princeton Radio Research Project in New Jersey, as well as with Hanns Eisler (1898–1962) in *Composing for the Films* (1947). The Princeton Radio Research Project was made possible by funding from the Rockefeller Foundation in 1937, and the Institute for Social Research also had a hand in it. Horkheimer suggested to Lazarsfeld that he bring in Adorno to work on the project. When Adorno first moved from London to New York in 1938, he spent half of his time working for the Institute for Social Research and the other half working for the Princeton Radio Research Project. His stay at the Radio Research Project ended in 1941.

Eventually, Adorno emerged as a leading member of the Institute, and such a fact had consequences for the further development of critical theory at the Frankfurt School. Adorno's full entrance into the inner circle of the Institute meant that Horkheimer turned his attention to him and his enormous working capacity. In Adorno, Horkheimer saw a possibility to realize the project which he was dreaming of,

which was a project on dialectical philosophy. Marcuse up to this point had been the natural partner for Horkheimer in philosophical concerns, but when Adorno fully entered into the theoretical work of the Institute, he, rather than Marcuse, became Horkheimer's chief ally. The idea behind the critique of positivistic science, which was strongly influenced by Adorno, was introduced in the articles of the 1937 issue of the *Zeitschrift*. It was in the years following those articles that Horkheimer's close collaboration with Adorno developed. Such phase of critical theory at the Frankfurt School was a continuation of the arguments from its preceding phase, but took on a form which transcended the arena of science and was extended to a total critique of civilized reason. Horkheimer wrote *Eclipse of Reason* (1947) and *Critique of Instrumental Reason* (1967) on his own after collaborating with Adorno in the writing of *Dialectic of Enlightenment*.

By 1950, Horkheimer had reestablished the Institute in Frankfurt. By that time, Adorno and Horkheimer were the Institute's two undisputed leaders in critical theory. In the course of time, Horkheimer's productivity declined while Adorno had his most productive years in the 1950s and 1960s. In 1955, without giving up his influence, Horkheimer decided to share his directorship of the Institute with Adorno in a cooperative directorship. Adorno was highly visible and vocal as a public intellectual in Europe, engaging in the positivist dispute in German sociology and a critical dialogue with philosopher Karl Popper (1902–94). In addition, he wrote a polemic of the existentialism of philosopher Martin Heidegger (1889–1976), *The Jargon of Authenticity* (1964), and wrote *Negative Dialectics* in 1966, where he both continued his critique of Heidegger and extended *Dialectic of Enlightenment*'s critical theory. His *Aesthetic Theory* was posthumously published in 1970. In the postwar Germany after 1945, in the context of the return of 'the Frankfurt School' to Frankfurt itself, Adorno rose to become the public face of the Institute, which in turn rose to public prominence.

History of the Frankfurt School II: From 1970 to the Present

The New Beginning with Habermas

However, despite the comprehensiveness of the first program of 'critical social theory,' the initial founding paradigm – centered around the combination of Marx and Freud via an explanation of current forms of capitalist power – also entailed major problems. It is largely to the credit of one major social theorist, Jürgen Habermas, to establish his work as well as person as a new turning table, as a discursive and organizational medium in which these problems could be redefined and addressed. Habermas thereby managed to preserve the spirit of critical theory by advancing it through entirely new conceptual and methodological means. Habermas ascent to the leadership position of the so-called second generation of the Frankfurt School is prepared through his early influential work in the 1960s. Here, Habermas, a generation younger than the founders, established himself as an equal member of the now increasingly recognized 'Frankfurt School' by basically two practices. First, Habermas made himself a name in a set of important debates. He comes to Adorno's aid in the famous positivism debate with Popper, coining influential terms like the one about Popper's positivistically reduced concept of reason. Similarly, he engages in well-known debates with the most established figures of postwar Germany in philosophy and social theory, such as Hans-Georg Gadamer (1900–2002) and his philosophical hermeneutics, and Niklas Luhmann (1927–98) and his social systems theory. In these debates Habermas establishes himself as an apt critique of gaps and issues in both paradigms. Second, Habermas is able to present his own epistemological version of critical theory as based in human species-specific 'knowledge interests.' By suggesting that the natural sciences are grounded in the need and interest to dominate nature, the humanities are grounded in the need and interest for cultural and historical self-understanding, and the social sciences are grounded in the need and interest for emancipation from unjust social orders, Habermas situates critical social theory as a legitimate human endeavor next to other established scientific projects.

Yet the second generation of the Frankfurt School is borne only when Habermas abandons his own early theory for the sake of a 'paradigm change of critical social theory,' which leads to the 'theory of communicative action.' In a well orchestrated and not modest self-installation as the savior of critical theory via its complete conceptual overhaul, Habermas engages in a new beginning, triggered by the widely diagnosed problems of his earlier conception, which among other issues conflates the epistemological-transcendental critique of grounds of knowledge with a social-normative critique of society. In fact, the issue of the lack of an adequate conceptualization of the normativity of social criticism becomes the hallmark of the second generation and Habermas' lasting contribution to critical theory.

The Theoretical Core of Communicative Reason

Habermas comes to define the second generation of the Frankfurt School. He renews this tradition of social critique, of critical social theory by breaking with its conceptual framework. Instead of the Hegel–Marxian dialectic of enlightenment, in which 'reason' – which once meant to liberate and emancipate the subject from its objective determinants – becomes transformed into its opposite, *reason* for Habermas is now reconstructed as a linguistically mediated potential of a historically evolving human society. This potential for a rationalization of our linguistic practices can be unleashed in two diametrically opposed ways: either as the instrumental thinking that permeates functional systems like the capitalist economy and modern administrative power, or as the intersubjective orientation at communicative processes in which all agents are respected as equal, valuable, and knowledgeable contributors. Habermas now grounds the emancipatory potential of *modernity* – as he prefers to designate his indebtedness to the legacy of the Enlightenment – in the in-built presupposition of the validity of speech in social communication. This allows one to see that the reflexive distanciation from tradition is defined by a dialectic that does not turn reason per se into its dominating opposite. It rather defines rationalization as enabling two different processes, either as functional or as communicative reason. The modernization and rationalization of society since the Renaissance now

enables a liberation from tradition that can lead either to functionalist thought *or* to communicative action. For Habermas, this dialectic defines an open, contested, and challenging choice for modern societies. Instead of being doomed by a dialectic of Enlightenment according to which reason turned into its opposite, we are now called to actively participate in the reconstruction of the full scope of reason so as to avoid succumbing to functionalism and other objectifying and anticommunicative forms of power.

Habermas' communicative turn in critical theory proved to be successful as the new conceptual face of critical theory. Four reasons largely account for this success. First, the theory of communicative action can justify its own critical normative orientation. Horkheimer and Adorno's position had left unclear how a totally dominated agency can still rebel and revolt, and how a completely destroyed enlightenment can still speak of enlightenment values like autonomy, truth, and equality. Second, Habermas' theory represents an unparalleled achievement of theoretical synthesis. The over 1000 pages of the two-volume *Theory of Communicative Action* (German 1981, English 1983/87) integrate the major sociological classics, argumentation theory, critical theory, and speech act theory to a new conception of validity-based communicative action. Third, Habermas' theoretical product appears at a time when the globalization of theory production takes off. Habermas' theory draws as much on American as on German sources, including Charles Sanders Peirce (1839–1914), George Herbert Mead (1863–1931), and Talcott Parsons (1902–79), and generally speaks to the new cosmopolitan class of social and cultural theorists who emphasize language, discourse, and a politics of recognition in the public sphere, the latter being one of Habermas' central concepts and research topics. Fourth, Habermas has been supported by several influential scholars, such as Albrecht Wellmer, Karl-Otto Apel, and Thomas McCarthy. Besides those, the second generation also includes thinkers like the Adorno's student Alfred Schmidt (1931–2012). Wellmer and Schmidt, along with others, some who would in later certain readings of the school find themselves regarded as members of the third generation at the Institute, contributed to an increasing academic as well as public recognition of the Frankfurt School as one of the most important German philosophical movements of the twentieth century.

Establishing the Communicative Paradigm and the Historization of the Frankfurt School

The brief conceptual sketch allows us to see how Habermas could indeed establish his communicative proposal at the center of a renewed critical theory. Yet as Bertolt Brecht rhetorically asked the historian who wrote that Caesar crossed the Alps: "Did he not at least have a cook with him?" we should note that Habermas did not do this on his own. Indeed, Habermas is an authorial center of discourse, as the actual author of the most influential books on the communicative turn; he is also the organizational center as the director of the Max Planck Institute for Social Research in Starnberg, which he codirected from 1969 to 1983; and he becomes, after the deaths of most the old guard in the late 1960s to mid-1970s, the increasingly famous living representative of the Frankfurt School. Yet on every account, the communicative turn is the work of many colleagues and contributors; it is impossible to conceive without such context and support. Theoretically, the transcendental pragmatics of philosopher Karl-Otto Apel (1922–present) gave essential insights, as did the analytic rigor and pragmatist acumen of American philosopher Thomas McCarthy (1940–present). Institutionally, the Starnberg Institute gave Habermas the resources to assemble some of the world's most relevant philosophers and social scientists in a uniquely productive interdisciplinary atmosphere. And finally, Habermas was a public persona who drew attention to his rather academically articulated theory. His important public standing emerged from his constant historico-political interventions which related him, at times antagonistically, to the student revolt of 1968 and the new democratic Germany; also important for Habermas' reputation were his at-times heated engagements with some of the most prominent post-structuralists and postmodernists, which include his highly visible critique of post-structuralism, especially with regard to Michel Foucault (1926–84) and Jacques Derrida (1930–2004).

With the death of Adorno in 1969, the withdrawal of Horkheimer to Switzerland around that time, Habermas' move to Starnberg in 1969, and with Marcuse and Löwenthal faraway in sunny California, the actual Institute for Social Research in Frankfurt became a rather modest center for social-empirical research. Under the able but unassuming directorship of Ludwig von Friedeburg (1924–2010), also minister of culture for the state of Hesse, solid social research projects were carried out. When the real action had moved elsewhere, the Institute for Social Research became an historical site of the imaginary entity of the Frankfurt School. What set in during the 1970s, besides the Habermasian paradigm shift and renewal, was the historization of the Frankfurt School as one of the most important twentieth-century movements in German philosophy and social theory. Rather marginalized as it was before the Second World War, and still long after, the Frankfurt School now became an object of historical desire, a piece in the mosaic of a new Germany that desperately searched for a new identity beyond Hitler. Works by Helmut Dubiel, the Californian Martin Jay, and the path-breaking volume by Rolf Wiggershaus defined this historical turn. Despite the dangers that were associated with such a historization, this move brought the first generation of Horkheimer, Adorno, Benjamin, etc., back into academic and public consciousness. It enables up until today to see critical theory as what it really is a complex and diversified project in which a multiplicity of approaches and methodologies come to bear to analyze the dialectic of human freedom and equality against the real backdrop of social power and domination.

Habermas returns to the Johann Wolfgang von Goethe Universitat in Frankfurt in 1983. The move comes after turning down offers from the University of California, Berkeley and Northwestern University and is well calculated: while Habermas does not formally assume the directorship of the still existing *Institute for Social Research*, he inhabits the University Philosophicum right next to it. The return of the master reinvigorates the historical awareness of the Frankfurt School, albeit Habermas aims to build his reputation as the undisputed king of critical theory by three essential and independently pursued projects. First, he writes *The Philosophical Discourse of*

Modernity, a book of questionable value as it is written in a largely polemical tone similar to Georg Lukacs' equally one-sided *Destruction of Reason*. Habermas blames the Nietzsche/Heidegger turn in contemporary French philosophy for the flaws to be found in Foucault, Derrida, Jean-François Lyotard (1924–98), and the like. Second and much more constructive is his work on a 'discourse ethics' which achieves a strong worldwide reception. Finally, and of perhaps the most sustaining influence, is his work on a new 'Rechtsphilosophie,' a 'philosophy of right,' culminating in *Facticity and Norms*, where he develops a democratic-theoretical account of the complex intertwinement of morality and law. Habermas also leads during this decade the famed Monday Colloquium where many of the best German and international, young and established, critical theorists presented and discussed their work in progress. The years from the mid-1980s to the mid-1990s, when Habermas retired from his Frankfurt post to teach on occasion at Northwestern, New York University, and elsewhere, define the coming of age of critical theory and its ascent to one of the world's most known traditions on social theory.

The Third Generation: Recognition, Feminism, Justice

The sustained productivity of the Frankfurt School can be measured by the fact that a third generation of influential and prolific authors is currently carving out new intellectual space for critical theory. While critical theory has justly become a term with much wider application than the initial Frankfurt School tradition, representatives that directly draw from it nevertheless exist and include social theorists such as Axel Honneth. Honneth is unique since with him, for the first time since the demise of Adorno in 1969, a major social philosopher both represents the philosophical heritage and organizationally heads the actual *Institute for Social Research*. Honneth succeeded Habermas on his chair for social philosophy in Frankfurt, and shortly afterward also assumed the directorship of the Institute. Honneth's increasingly influential theory of recognition builds on insights from the early Hegel and G.H. Mead in order to construct a threefold understanding of recognition: love or emotional recognition, respect or moral recognition, and esteem or sociocultural recognition represent for Honneth, three anthropologically deep-seated needs the fulfillment of which agents require to fully develop as autonomous selves; conditions that withhold such fulfillment can be understood to fuel social struggles for recognition. Emotional recognition builds self-confidence, moral recognition self-respect, and cultural recognition self-esteem – all three of which together define an ethically acceptable and good life for which agents fight if the conditions for their realization are withheld from them. The communicative recognition that Habermas grounded in argument-based validity claims thus receives a deeper and more social-philosophical and social-historical basis. Honneth advances a truly critical-theoretical approach, as such a perspective – since the early Frankfurt School – has always consisted in combining a normative orientation toward more justice and freedom with an analysis of the social-historical and empirical grounds that would enable its realization practically. As Institute director as much as social philosopher, Honneth searches for constant dialogue and expansion with related critical-theoretical approaches. This led to a much noted exchange with Nancy Fraser in *Redistribution or Recognition?* in which the focus on moral and cultural recognition is challenged by the continued structural need for economic justice. Nancy Fraser and Seyla Benhabib represent third generation critical theorists who in a distinctively feminist vein approach issues of identity, power, gender roles and justice, as well as globalization and cosmopolitanism – besides also internationalizing critical theory in person. Closely affiliated with Axel Honneth, and important because of his work on G.H. Mead, Hans Joas may also be seen to make an important contribution. All these thinkers represent potent voices in an increasingly transnational theory discussion over the right approach to the social-political challenges from a normatively informed view.

There are in fact different strands or readings of who else belongs to the third generation, both in Germany and internationally, and some in sociology and social and political theory more than philosophy. Joas is at times read into the tradition of the third generation in social theory. With the increasing internationalization of critical theory and with a look at theoretical developments of both Habermas' discourse ethics and Axel Honneth's theory of recognition, Nancy Fraser's and Seyla Benhabib's work has become a constitutive part of a third generation's critical theory. Claus Offe and Oskar Negt are in certain readings, especially but not only in Germany, also regarded as third generational. Offe's monographs first started to appear in 1965. Since then, he has engaged contemporary conceptions of the welfare state and its implicit contradictions, and has characterized late capitalism as disorganized. Negt, who trained under Adorno and then went on to serve as an assistant to Habermas, has further developed Habermas' notion of the public sphere and has embarked on a theory of history in his more philosophical writings.

Honneth and with him Joas, Offe and Negt, and Fraser and Benhabib are among the most prominent contributors of the third generation of a school the influence of which is, however, much more widespread and sustained than the mentioning of these names could capture. Noteworthy are also recent attempts to transgress and cross-over between different paradigms of critical theory, which includes building bridges between the Frankfurt School in all its versions and British Cultural Studies, French Post-Structuralism, and contemporary social theory in all of its different forms. Besides the original Institute of Social Research, which continues to exist under its current director Axel Honneth, several important venues of exchange and research grounded in the Frankfurt School critical theory have sprung up in recent decades: The American Critical Theory Roundtable, the Prague Conference of the Social Sciences, and the Frankfurt University Research Cluster Normative Orders. Critical social theory, as conceived by its original founders, did care little about discursive boundaries or school designations; its aims has been to advance critical reflexivity with regard to the most pressing and least understood currents of our contemporary and continuously unjust social orders. Its motto was and is the critique of the social status quo by any theoretical means necessary, with the aim to be able to conceive its practical overcoming. Unfortunately, due to the continued pervasive influence of power, oppression, and ignorance, critical social theory and the project of

the Frankfurt School has lost nothing of its urgency in today's world.

Abstract

This article discusses the history of the ideal of political freedom from ancient times to the present day. Prior to the seventeenth century, political freedom was widely understood to mean not having a master, but the value and feasibility of this good was contested. Hobbes introduced the 'negative' conception of freedom as noninterference in the seventeenth century, and Rousseau introduced the 'positive' conception of freedom as effective self-mastery in the eighteenth century. The debate between these two conceptions has dominated discussions ever since, obscuring the older and once widely shared view.

This article discusses the history of the political ideal of freedom or liberty, that is, what it means for a person or group to enjoy freedom or liberty in the political sense. (Freedom and liberty are simply two words for the same concept, the first of Germanic and the second of Latin origin; they will here be used interchangeably.) This article will thus not discuss freedom of the will and determinism, or what was at one time debated under the heading of 'liberty and necessity'.

As is well known, the meaning of political freedom is presently the subject of much debate among political theorists and philosophers. Remarkably, this was not always so. Indeed, prior to the late eighteenth century, its meaning was debated relatively little, and prior to the mid-seventeenth century, scarcely at all. This is not to say that there were no vigorous debates about freedom or liberty before that time; quite the contrary, as we shall see. But these debates generally did not concern what it *meant* for a person or group to enjoy freedom in the political sense.

Historical Origins

For a person or group to enjoy freedom or liberty in the political sense, on the long-standing standard view, was simply for them to enjoy a certain sort of independence. Roughly speaking, freedom was understood as the sort of independence enjoyed by an individual who, not being a slave, serf, bondsman, or servant, does not have a master, and so is a 'free person', or, analogously, the sort of independence enjoyed by a community that does not live under the rule of an autocratic king, tyrant, oligarchy, or foreign empire, and so is a 'free people'. In part because the meaning of political freedom was not itself the subject of controversy, its precise scope remained vague and open-ended. It was a negative ideal, in the straightforward sense that to enjoy freedom was simply *not* to have a master of one sort or another.

This traditional conception of political freedom or liberty had its roots in the ancient world. In Greece, freedom (*eleuthera*) was viewed as the independence men and women feared to loose if they were captured in war or succumbed to debt and thus became slaves. In the *Iliad*, Hektor tells his wife that he is troubled less by the prospect of Troy's fall than by

> …the thought of you, when some bronze-armored Achaian leads you off, taking away your day of liberty, in tears; and in Argos you must work at the loom of another…unwilling, but strong will be the necessity upon you.
> (p. 165)

Freedom was analogously understood as the self-rule of independent city-states that Athens and her allies defended at Marathon and Salamis against Persian imperialism. Thus, according to Herodotus, a Spartan explained to a Persian that

> You understand well enough what slavery is, but freedom you have never experienced, so you do not know if it tastes sweet or bitter. If you ever did come to experience it, you would advise us to fight for it not with spears only, but with axes too.
> (p. 413)

At Rome, liberty (*libertas*) was thought to have been established when the Tarquins were expelled, briefly endangered when the decemviri tried to seize permanent authority for themselves, and finally lost in the dissolution of the Republic by the Caesars. Cicero, for example, observes that

> …if the people hold to their own rights, they deny that there is anything more outstanding, more free, more blessed …. [A]nd so it is usual for the "concern of the people" to be liberated from the domination of kings and aristocrats, and not for kings or the power and wealth of an aristocracy to be sought by a free people.
> (p. 21)

Historically speaking, philosophical interest in freedom or liberty was greatest when it was most felt to be in danger. It is most energetically extolled in Herodotus' and Aeschylus' writings on the Persian wars, or by Aristotle and Demosthenes as the independent city-states fell under Macedonian rule, for instance. Similarly, most Latin reflections on liberty come from around the time of the collapse of the Republic, especially in the works of Cicero, Sallust, and Livy. After centuries of relative disinterest, a similar pattern can be observed in the Renaissance: although independent city-state republics populated northern Italy for much of the Middle Ages, only in the fifteenth century – as their self-rule faced increasing domestic and foreign challenges – did Bruni, Rinuccini, and Machiavelli pen their panegyrics to freedom and liberty.

It was this traditional conception that the early-modern English political writers inherited. While they were certainly well read in the classical and Renaissance sources that we have mentioned, the text that – directly or indirectly – informed them most profoundly was not produced by a political theorist at all. It was rather the *Corpus Iuris* of Justinian that for centuries fixed the meaning of liberty in Western political thought. Early on, the *Digest* states flatly that all law concerns persons, things, or actions, and that the main distinction among persons is that between those who are free on the one hand, and those who are slaves on the other. This sharp contrast between freedom and servitude is reiterated again and again in the *Corpus*, and constitutes one of its fundamental conceptual legacies. It is hardly surprising, then, that it was above all to this notion of freedom that writers like Milton, Harrington, Sidney, and Locke unconsciously and repeatedly turned during England's constitutional struggles of the seventeenth century.

Now while there was little dispute concerning what it *meant* to enjoy freedom, there were many significant debates *about* freedom. Two controversies in particular frequently recurred. The first was normative, and concerned how highly freedom should be valued relative to other important social or political goods. While perhaps a majority of the ancients regarded freedom very highly indeed, there were always some dissenting opinions: Plato, for instance, argued vigorously in the *Republic* that justice was far more important than the freedom enjoyed by the citizens of a democracy. During the Middle Ages, advocates for the priority of freedom were decidedly in the minority. Far more important than freedom, argued Augustine, Aquinas, and many other writers, was peace and order. Debates concerning the relative value of freedom continued in the Renaissance and after. Castiglione illustrates the debate clearly in the fourth book of his *Book of the Courtier*, where one character argues that a free republic is the supreme gift of God, while another replies that a tranquil monarchy is more consistent with living a dignified life in peace and quiet.

The second recurring controversy was empirical. It concerned how much freedom could be safely enjoyed without undermining social order. Especially after the defeat of Athens in the Peloponnesian War, it was widely assumed that too much unstructured independence could be self-defeating, and thus self-government needed to be carefully balanced and contained within the framework of what Polybius termed a 'mixed constitution'. Subsequent advocates for political freedom, from Cicero to Machiavelli to Montesquieu, were all insistent that its preservation depended on maintaining a balanced political system and a strict rule of law. Critics of freedom, such as William Barclay and Robert Filmer, remained unconvinced that such a system could be self-sustaining; a society of 'masterless men', they believed, must necessarily slide into chaos.

Both these debates and others, however, revolved around a conception of freedom or liberty that was largely uncontroversial. While the relative value or practical feasibility of political freedom might be contested, it was largely taken for granted that everyone understood the idea under discussion: to be free was, plain and simple, to have no master.

Hobbes and Rousseau

Two great political thinkers, from the seventeenth and eighteenth centuries, were primarily responsible for upending the traditional understanding of political freedom and throwing its meaning into doubt. These thinkers were, respectively, Thomas Hobbes and J.-J. Rousseau.

Perhaps to a greater extent than any previous thinker, Hobbes recognized both the power, and also the mutability, of definitions. Writing during the English Civil War, and fervently believing that only the general recognition of an absolute sovereign could deliver an end to the conflicts of his day, Hobbes faced a peculiar challenge. On the long-standing traditional view, political freedom and absolute sovereignty are strictly incompatible. The advocates of limited sovereignty and commonwealth government accordingly leaned heavily on the powerful rhetorical appeal of freedom. Machiavelli had indeed observed the force of this appeal some time before:

> Whoever becomes the master of a city accustomed to freedom, and does not destroy it, may expect to be destroyed himself; because, when there is a rebellion, such a city justifies itself by calling on the name of liberty …never forgotten despite the passing of time and the benefits received from the new ruler.
> (p. 18)

In order to diffuse this rhetorical appeal, Hobbes sought a conception of freedom that, contrary to all previous understanding, could be shown compatible with absolute sovereignty. He found his answer in what is now widely called the 'negative' conception of freedom.

On the negative conception of freedom, we are free to the extent that we are merely not interfered with by others. There have been many variations on this conception since Hobbes, depending on how exactly one chooses to define 'interference' in the relevant sense, but they all have in common the basic intuition that to be free is, more or less, to be left alone to do whatever one pleases. Now of course the value in being left alone had long been recognized; contrary to popular opinion, even the ancients were perfectly well attuned to this value. Thus Thucydides recounts that Pericles approvingly remarked of Athens that

> …just as our political system is free and open, so is our day-to-day life in our relations with each other. We do not get into a state with our next-door neighbor if he enjoys himself in his own way ….
> (p. 145)

But it was always recognized that an absence of interference – sometimes termed 'license' – is not at all the same as freedom or liberty in the political sense. (Indeed, it was pointed out by Machiavelli and others that too much of the former could actually undermine the latter by eroding the rule of law.) The two ideas are distinct because, while the traditional view of freedom is indeed 'negative' in the simple sense described earlier of consisting in the absence of something, having a master might easily be consistent with enjoying a considerable degree of noninterference. An imperial power might, for

example, refrain from interfering much with the local administration of its colonies, and yet those colonies do not, on the traditional view, thereby enjoy political freedom.

This last point is especially significant because it answers precisely to Hobbes's aims. On the new negative conception, as he says, political freedom is merely the "silence of the laws" (p. 146), and there can be as many or as few laws under any one form of government as under any other. Thus, he infers, there can be no logical grounds for objecting to absolute sovereignty on the basis of political freedom:

> There is written on the turrets of the city of Lucca in great characters at this day, the word libertas; yet no man can thence infer, that a particular man has more liberty, or more immunity from the service of the commonwealth there, than in Constantinople. Whether a commonwealth be monarchical, or popular, the freedom is still the same.
> (p. 143)

By redefining political freedom in this way, he hoped to defang the most potent objection to absolute sovereignty.

Not surprisingly, Hobbes's new conception did not immediately take hold. James Harrington among others quickly recognized the sleight of hand and pointed it out:

> The mountain has brought forth, and we have a little equivocation! For to say that a Lucchese has no more liberty or immunity from the laws of Lucca than a Turk has from those of Constantinople, and to say that a Lucchese has no more liberty or immunity by the laws of Lucca than a Turk has by those of Constantinople, are pretty different speeches. The first may be said of all governments alike, the second scarce of any two; much less of these, seeing it is known that whereas the greatest bashaw is a tenant, as well of his head as of his estate, at the will of his lord, [while] the meanest Lucchese … is a freeholder of both ….
> (p. 20)

For some time thereafter, the negative conception of freedom remained no more than an intellectual curiosity. A generation later, we find an especially clear statement of the traditional view reiterated in John Locke: freedom is not "a liberty for every one to do what he lists", he writes, but rather "to have a standing rule to live by" and "not to be subject to the inconstant, uncertain, unknown, arbitrary will of another man" (p. 110). Indeed, the traditional conception remained dominant well into the eighteenth century, as is clear from a reading of *Cato's Letters*, Blackstone's *Commentaries*, or the pro-American pamphlets of Priestly, Price, or Paine. Only much later, as we shall see below, did Hobbes's negative conception of liberty catch on.

In the meantime, we must consider the second major challenge to the traditional conception of freedom, this one raised by Rousseau. Like Hobbes, Rousseau was interested in showing that freedom is consistent with absolute sovereignty – provided, on his version of argument, that the sovereign is the whole body of citizens. This he does by drawing a distinction between what he terms the "natural liberty" enjoyed in the state of nature on the one hand (roughly, the negative liberty of Hobbes), and what he terms the "civil liberty" enjoyed through community on the other. The latter he defines as "obedience to the law one has prescribed for oneself" (p. 151). This has come to be known as the 'positive' conception of freedom.

The positive conception of freedom is more difficult to characterize with analytic precision than the negative. Roughly speaking, persons or groups are free in the positive sense to the extent that they exercise some degree of self-control or self-mastery. It is not agreed, however, what exactly constitutes self-mastery in the relevant sense. According to one particularly influential account, offered by Harry Frankfurt, to be free in the positive sense is to be able to act on one's second-order desires. For example, the addicted gambler may be free in the negative sense not to gamble (no one forces him to gamble), but he is not free in the positive sense unless he can actually succeed in acting on his second-order desire not to desire gambling. Applied to the political sphere, we can see that something like this thought animates Rousseau's conception: "to be driven by appetite alone", he says, "is slavery" (p. 151). It follows that, when the community as a whole compels one of its members to realize some second-order desire, he is merely "forced to be free" (p. 150).

Rousseau no more invented his distinctive conception of freedom out of whole cloth than did Hobbes. From the time of the Stoics, it had been commonplace to use the language of freedom and slavery when discussing the struggle to master one's own passions and desires. This language was adopted by early Christian writers, who frequently contrasted the 'slavery of sin' with the 'freedom of righteousness', a popular formula down to the time of Martin Luther's famous tract on "The Freedom of a Christian" and beyond. This usage was always clearly metaphorical, however. It was never suggested that freedom or liberty in the *political* sense should be understood in this manner. Indeed, the force of the metaphor in discussions of personal ethics was parasitic on the standard view of political freedom as consisting in the absence of a master. It was Rousseau (anticipated perhaps by Spinoza, but with little consequence for respectable opinion) who first advanced the positive conception as an account of *political* freedom, with remarkable consequences for the history of political thought, as we shall see.

III

In June 1789, representatives of the Third Estate abandoned the Estates-General and declared themselves the National Assembly of France. Together with the storming of the Bastille by the people of Paris in July, these events initiated what would become a quarter century of revolution, international war, and social turmoil in Europe – an experience that naturally had a great many consequences for the history of political thought generally, and for the concept of freedom or liberty specifically. When during the darkest days of the revolution the Committee of Public Safety subjected France to a reign of terror, it did so in the name of *Liberté, égalité, fraternité*. When Napoleon's armies spread across Europe, they did so in the name of revolutionary liberation. What were people to make of these proclamations?

Reflecting on such events a few years after peace had finally been restored, Benjamin Constant delivered a famous and influential speech on 'The Liberty of the Ancients Compared

with that of the Moderns'. The societies of ancient Greece and Rome, he argued, were very different from our modern societies. They were small, tight-knit communities; their relative vulnerability meant that military affairs necessarily loomed larger than commercial affairs; and their employment of slave labor provided citizens with ample leisure. It is only to be expected, he said, that the ancients would understand political freedom in a manner reflecting their circumstances. For them, freedom meant "exercising collectively, but directly, several parts of the complete sovereignty" of the community as a whole. This they were able to do only because their societies were relatively small and because they enjoyed sufficient leisure time in which to dedicate themselves to public affairs. However, "the complete subjection of the individual to the authority of the community" is "compatible with this collective freedom". In the ancient societies, Constant claimed, no "importance was given to individual independence" (p. 311).

Modern societies are entirely different from ancient ones. They are large, diverse, and impersonal; commercial interests predominate over military interests; and of course, the practice of slavery has been abolished. The moderns, Constant said, have a very different conception of political freedom, better suited to their own times. On this modern view, freedom is simply

> …the right of everyone to express their opinion, choose a profession and practice it, to dispose of property, and even to abuse it; [and] to come and go without permission, and without having to account for their motives or undertakings.
> (pp. 310–311)

It is immediately apparent that what is being described here is the negative liberty of Hobbes – the freedom to be left alone, without outside interference. Negative liberty, Constant claims, is the only sort of freedom suitable to modern conditions. The excesses of the French Revolution arose precisely from the futile dream, inspired by Rousseau, of reviving positive liberty of the ancients in modern times.

His diagnosis proved extremely influential. Many writers soon embraced enthusiastically the negative conception of freedom as noninterference, among them Jeremy Bentham and William Paley. Their combined influence was such that by the time J.S. Mill wrote his essay *On Liberty* in the 1850s, he could write without pausing for debate that "the only freedom which deserves the name, is that of pursuing our own good in our own way, so long as we do not attempt to deprive others of theirs" (p. 17). The negative conception of freedom is clearly the dominant view today, particularly among Anglo-American political theorists and philosophers. Of course, there has been a dissenting minority who did not give up on Rousseau's dream – Hegel, for instance, and some other continental philosophers. Later supporters of the positive conception of liberty include the English Hegelians like T.H. Green, and more recently, some communitarians like Charles Taylor, but these writers have never been able to overturn the dominance of the negative view.

Nearly a century and a half after Constant, Isaiah Berlin delivered an even more famous lecture reviewing the debate between positive and negative freedom, 'Two Concepts of Liberty'. Berlin reiterates Constant's warning against the dangers of positive liberty. "It is one thing to say that I may be coerced for my own good which I am too blind to see", he says.

> [T]his may, on occasion, be for my benefit …. [But] it is another to say that if it is my good, then I am not being coerced, for I have willed it, whether I know this or not, and am free (or 'truly' free) even when my poor earthly body and foolish mind bitterly reject it, and struggle against those who seek however benevolently to impose it ….
> (p. 134)

This warning is, no doubt, well heeded. What is peculiar about Berlin's lecture, however, and about the earlier one by Constant on which it was (consciously or unconsciously) based, is that the positive conception of liberty attributed to the ancients was not in fact the understanding of political freedom to which they – nor indeed anyone, prior to Rousseau – subscribed. Negative liberty is held up as the political ideal much safer than its positive alternative, without apparently recognizing that both are modern inventions.

What explains this peculiar turn of events? One possibility, of course, is simply that the magnetic power of Rousseau's political writings sewed the confusion. For subsequent writers, 'the ancients' simply became the ancients as Rousseau imagined them, and the 'freedom' they enjoyed the conception of freedom Rousseau extolled: both those attracted to his vision and those repelled by it could no longer see past it clearly. Another possibility, however, is that deeper interests were at work. The early nineteenth century was a period in which the working classes, servants, women, and national minorities were steadily forcing themselves onto the political stage. Combining the traditional view of freedom or liberty with a more inclusive political ethic would have potentially revolutionary consequences, as a few writers astutely recognized: it would mean granting independence from mastery to women, to servants, and so forth. Thus William Paley suggests that

> …those definitions of liberty ought to be rejected, which, by making that essential to civil freedom which is unattainable in experience, inflame expectations that can never be gratified, and disturb the public content with complaints, which no wisdom or benevolence of government can remove.
> (p. 315)

Far less disruptive to the social order is the negative conception of political freedom which, as we have seen, is perfectly consistent with mastery so long as that master lets one alone. On this second reading of intellectual history, the positive conception of political freedom was little more than a convenient straw man.

Although the negative freedom–positive freedom dichotomy continues to shape discussion among contemporary political theorists and philosophers, there has recently been a revival of interest in the traditional view. Beginning primarily with historical work on Machiavelli and the classical republican tradition, and increasingly branching out into areas of contemporary normative political philosophy, Quentin Skinner, Philip Pettit, and others have challenged the conceptual topography laid

down by Constant and Berlin, and it is difficult to foresee where the debate will go from here.

Abstract

This article defines press freedom-related concepts and theories. In addition, it examines various key issues relating to freedom of the press in the United States and abroad. Among the topics covered are censorship, international law on censorship, self-censorship, right of reply, press subsidies, licensing of journalists, defamation law, criminal defamation, transnational defamation litigation, Internet defamation, preventive counseling, freedom of information, free press vs fair trial, journalist's privilege, and US press freedom in the global twenty-first century.

No press system is absolutely free from various social, political, economic, or legal controls of its society. Most discussions of freedom of the press center on the relationship of government and the press, and here the basic question is not whether government controls the press but how and to what extent. Freedom of press refers to negative freedom – freedom from governmental constraint, or it may refer to positive freedom – the capacity to do or achieve certain ends. In liberal rule-of-law democracies, most issues concerning press freedom have revolved around negative freedom understood as the independence of the news media from governmental restraint. Hence, private censorship by the corporate news media has rarely been a legal issue. But it has taken a heightened urgency. In September 2012, for example, Google's handling of the controversial anti-Islam video 'The Innocence of Muslims' in the United States and abroad showcased the American Internet company's global role in arbitrating free speech issues in the twenty-first century (Benesch and MacKinnon, 2012).

The Term 'Press'

The 'press' in 'freedom of the press' is elusive. The general public considers the word press as the conventional institutional news media, including newspapers, magazines, and radio and television broadcasters. However, the popular image of the term press is too limiting to reflect the press in general, especially in the age of 'citizen journalism,' a new form of journalism that has no connection with the institutional media. Regardless, the US Supreme Court noted in the late 1930s: The press goes beyond mainstream newspapers and magazines to 'every sort of publication which accords a vehicle of information and opinion' (*Lovell v. Griffin*, 1938). Can the term press be distinguished from 'speech' in 'freedom of speech'? Thus far, the answer to the press–speech dichotomy question is 'no' in US law. The now well-established US rejection of the distinction between press and nonpress communicators presents a striking contrast to the clear-cut statutory recognition of the press in continental Europe and some Asian countries. It should be emphasized, however, that the presence (or absence) of a direct press law does not necessarily ensure a privileged (or unprivileged) press in a country.

The breathtaking technological advances are challenging the traditional concept of the press. In the Internet era, more people say, 'We're *all* journalists' (Gant, 2007). The transformative communication technology belies the structure-centric notion of the press. The function and practice of the press in information gathering and dissemination should be more relevant than the institutional elements of the press. The Web 2.0-based 'citizen journalism' is a case in point. It is changing traditional journalism in so many ways, including 'crowdsourcing' and intended audience (Friedland and Kim, 2009). The influence of the blogosphere as part of citizen journalism is growing, and press freedom theories need to be refined or developed to explain why.

Theories of Press Freedom

In the sense of 'a reasoned explanation of why particular actions lead to certain outcomes' (Christians et al., 2009), various press freedom theories help to answer why press freedom exists. But "one's views on *why* [freedom of speech and the press] exists will tend to influence heavily one's views on *what* it means and *how* it should be implemented" (Smolla, 2014a).

The key values sought by society in protecting freedom of expression are that freedom of expression assures individual self-fulfillment; helps to discover the truth; secures participation by citizens in social, political, and economic decision making; and promotes a stable change in society (Emerson, 1970). The press is protected as the surrogate of the public when performing its informing and checking functions as a Fourth Branch supplementing the executive, legislative, and judicial branches of government.

The foremost value of press freedom comes from the premise that a press free from government control is essential to a political system based on the will of the people. The 'checking value' of a free press posits that the press should be guaranteed freedom to report abuses of power by public officials (Blasi, 1977). This compels a logical conclusion that the government should not prohibit the people from receiving news critical of the government.

Hence, when journalists publish classified information that whistleblowers have obtained illegally, they are not criminally prosecuted in American law. Under the source-reporter double standard in the United States, former National Security Agency (NSA) contractor Edward Snowden, who obviously violated laws in 2013 in leaking to the reporters of the *Washington Post* and other newspapers classified documents about the NSA's surveillance programs, is not protected by the First Amendment to the US Constitution on freedom of the press. But the

reporters who received Snowden's leaks for news reporting as their source are protected insofar as they did nothing illegal in accessing the classified NSA documents from him.

The checking value theory on press freedom has not been explicitly embraced by the US Supreme Court, especially in the reporter's right to refuse to identify news sources. Nonetheless, the European Court of Human Rights (ECtHR) expounded on freedom of expression as an 'essential foundation of a democratic society' and more specifically on the 'safeguards that a free press needs in serving its crucial role as a watchdog' (*Goodwin v. United Kingdom*, 1996).

The libertarian concept of press freedom most fully developed and most ardently supported in the United States focuses exclusively on negative freedom. Since the 1940s, it has been challenged by views that emphasize 'freedom for' as much as 'freedom from.' Concerned about the inexorably growing influence of the mass media on society, so-called social responsibility theories of the press have emerged as a significant counterpoise to the laissez-faire libertarian view. The increasing significance of broadcasting regulated by government 'in the public interest' from early on has no doubt contributed to this emphasis.

The criticism of a libertarian concept of press freedom stems from an innovative proposition that freedom of the press carries little meaningful value unless it is supported by an independence of editorial decision making from both internal and external pressures. In this context, 'journalistic freedom' also known as 'internal freedom' is distinguished from press freedom. Journalistic freedom is concerned with a relationship between the working journalists of a news medium and the managing executives and editors of the news medium. It is an individualized, not institutional, type of press freedom.

The News International phone-hacking scandal of the 2000s in England that centered on the now defunct *News of the World* illustrated the egregious lack of journalistic freedom *within* the news media organization. The UK newspaper's phone hacking, checkbook journalism, and other types of reporting malpractice had more to do with commercial abuse of press freedom as an institution than with its supposed pursuit of the public interest as a trusted watchdog. The scandal led to the 'Leveson Inquiry' (chaired by Lord Justice Leveson) in 2011 into the ethics and practices of the UK press and its future regulation. The resulting Leveson Report of 2012 proposed that the existing self-regulatory body, Press Complaints Commission, be replaced with a more independent body that would be empowered with a range of sanctions. The report has generated a great deal of controversy in and outside the UK press. But its value is associated with its various press-related proposals and also with its 'wealth of information' on the ethics, practices, self-regulation, and structure of the British news media industry (Special issue: Media law after Leveson, 2013).

As in the United Kingdom, press freedom in the United States is to a large degree guaranteed and practiced institutionally, but journalistic freedom is rarely accepted. By contrast, several free press countries in Europe and Asia try to accommodate the conflict between the institutional press freedom and the internal journalistic freedom. A case in point is South Korea, a formerly authoritarian polity but now a vociferous democracy. To ensure separation between the editorial department and management, the *Hankyoreh Shinmun* (One Nation Newspaper) and several Korean newspapers have reporters directly involved in deciding on the overall editorial policy of their newspapers with managing editors elected by reporters or selected from those recommended by them.

Censorship of the Press

In connection with press freedom, both institutional and journalistic censorship is an unending concern to the print and broadcast media around the world. Censorship, particularly if it is exercised by an administrative official with few procedural constraints, is fraught with so many vices against the press. Thus, judicial censorship via injunctions is viewed as 'more tolerable' than administrative censorship (Barendt, 2005).

Censorship is intertwined with power so inextricably that it is referred to as the 'handmaiden of power.' Censorship in the sense of prior restraint on the press is more effective than subsequent punishment because of its broader scope and lack of countervailing mechanisms, such as public appraisal of its rationale. It also has a propensity to decide against publication because "[t]he function of the censor is to censor. He has a professional interest in finding things to suppress" (Emerson, 1955).

Censorship can be total when all the media are systematically controlled. In the United Kingdom, courts may issue *contra mundum* orders against the news media not to publish the information covered. The orders bind any journalist or media organization that is aware of them. Also, 'super-injunctions' are granted by English courts to bar news organizations from reporting the very fact that they are subject to the judicial gag orders.

Administrative vs Judicial Censorship

The legality and scope of press censorship is sometimes examined by focusing on who primarily dictates the censorship mechanism. Is censorship entirely in the hands of executive officers with no judicial oversight? On this issue, the United States differs from Japan. The US law does not allow even court-issued prior restraint under the First Amendment. In Japan, however, the anticensorship principle does not extend to judicial restrictions because censorship is limited to administrative imposition of prior restraint on the press.

International Law on Prior Censorship

Prepublication censorship as an *administrative* action is incompatible with the free press principle in a democracy. This is explicitly recognized by the American Convention on Human Rights:

> The exercise of the right [to freedom of thought and expression] … shall not be subject to *prior censorship* but shall be subject to subsequent imposition of liability which shall be expressly established by law to the extent necessary to ensure:
> 1. respect for the rights or reputations of others; or
> 2. the protection of national security, public order, or public health or morals.

Self-Censorship of the Press

Self-censorship is viewed as a widespread and insidious problem among reporters and editors. Journalists resort to self-censorship when they decide to avoid legitimate stories, not because of their professional judgments, but on nonprofessional grounds. In some cases, self-censorship can be intimately intertwined with state censorship. This is the case in Israel: "When acting as concerned members of society, editors and journalists are of one mind with the censors concerning the prohibition of public exposure of issues considered crucial to the physical welfare of Israel or to its ideological raison d'etre (even though the public may not share that view)" (Liebes, 1997).

Intrusion of commercial interests into editorial decision making is another major cause of self-censorship. "Market forces are seen as the primary reason why worthwhile stories are not pursued and this factor is especially prevalent in the broadcast arena" reports a recent survey of American journalists on self-censorship (Kohut, 2000).

Self-censorship is closely related to threat of lawsuit for defamation, invasion of privacy, breach of confidentiality agreements, and related issues. Nearly 30 state anti-SLAPP (Strategic Lawsuit Against Public Participation) laws in the United States (no federal law) aim to prevent individuals or news media from being intimidated into self-censorship by litigious, well-financed business people or organizations. Most SLAPP lawsuits are meritless and lose, but their chilling effect on the news reporting on controversial issues is considerable. When sued, media defendants have to reallocate their limited money, time, and resources in defending the SLAPP lawsuits.

Right of Reply

Requiring news media outlets to allow the subjects of their reporting to reply or correct their stories does not necessarily transgress the free press principle if the obligations are not sweepingly broad or intrusive of the media's editorial independence. In the United States, however, the mandatory right of reply statutes governing the news media as a whole and the print press in particular are seen as violations of freedom of the press.

The US Supreme Court in 1974 struck down a right of reply statute on the ground that it would infringe upon the editorial rights of the press: "A newspaper is more than a passive receptacle or conduit for news comment and advertising. The choice of material to go into a newspaper and the decisions made as to limitations on the size and content of the paper and treatment of public issues and public officials – whether fair or unfair – constitute the exercise of editorial control and judgment. It has yet to be demonstrated how governmental regulation of this crucial process can be exercised consistent with First Amendment guarantees of a free press as they have evolved to this time" (*Miami Herald Publishing Co. v. Tornillo*, 1974).

In foreign and international law, however, the right of reply is increasingly accepted. More than a dozen countries in Europe, including Germany and France, recognize the right of reply. The right of reply in German law is derived from French law. The policy justifications for the right of reply in Germany are not so much to provide the public with access to the media as to protect individuals from false defamation. This differentiates German law from South Korean law on the right of reply. The right of reply in Korea is justified partly because it can contribute to the public's discovering truth and forming diverse public opinions by creating a more open marketplace of ideas.

Especially noteworthy is the international acceptance of the right of reply. The International Convention on the Right of Correction, the European Convention on Human Rights, and the American Convention on Human Rights provide for the right of reply.

The explicit recognition of the right of reply in several civil law countries in Africa, Asia, Europe, and Latin America, and under international law signifies that there are alternative visions of press freedom. This stands in sharp contrast with the US approach to the negative freedom of the press; that is, access to the press is not entirely antithetical to freedom of the press, but it can be viewed as a plausible 'positive' notion of press freedom in ensuring more opportunity for freedom of expression.

Press Subsidies

Amid the ongoing financial difficulties facing the legacy news media in the United States, which follows a minimalist public support model, governmental financial support for media operations and content has been a topic of considerable policy debate in and outside the media industry. Those who are wary of state subsidies for the press are concerned about the government's possible interference with journalistic work. However, their worry is likely misplaced, given the established First Amendment jurisprudence.

Also, evidence from the Scandinavian press subsidies disproves an assumption underlying the adversarial press–state relations in the United States that newspapers receiving direct public subsidies will lose their editorial independence and autonomy from the government. The Swedish subsidy program 'has had little effect on the willingness of subsidized publications to criticize government' (Gothberg, 1983; Gustafsson, 1980).

Licensing of Journalists

Government licensing of journalists is incompatible with freedom of the press as a basic human right. As the Inter-American Court of Human Rights (IACHR) ruled in 1985: "Such a law (on licensing of journalists) would contain restrictions to freedom of expression … and would consequently be in violation of not only the right of each individual to seek and impart information and ideas through any means of his choice but also the right of the public at large to receive information without any interference" (IACHR, 1985).

Defamation Law

Defamation was one of the earliest legal actions available against the press, and it is still the most common legal danger

to the media. Defamation is an occupational hazard for media professionals. About 70% of all American defamation actions are filed against the mass media; at least two-thirds of these actions are brought against newspapers in the United States. Defamation law protects the reputational interests of individuals because it involves the expression of opinions about them by others. It also attempts to compensate for economic and emotional injury and promotes human dignity by providing a civilized forum in which a dispute is settled. Most importantly, however, defamation law acts as a deterrent on the publication of false and injurious speech through the award of damages. In addition, defamation law serves a vital social interest by providing a check on media power. It opens the newsgathering and decision-making process of the media to public scrutiny and accountability.

Criminal Defamation

There is growing evidence globally, whether statutory or decisional, that criminalizing defamatory statements is contrary to a right to freedom of speech and the press. In the United States, however, 15 states and one US territory still have laws on the books that allow the government to prosecute people for criminal defamation. American criminal defamation law, which the US Supreme Court has not repudiated, stands in contrast with foreign law, in which libel is increasingly decriminalized. For example, criminal defamation has been abolished in England, Ireland, Mexico, and other countries. An in-depth empirical study of criminal defamation in the United States has stated: "Criminal libel can be especially useful for people of limited means, those who would have difficulty finding lawyers to pursue civil lawsuits for libel. Criminal libel may also be useful in curbing defamatory gossip on the Internet" (Pritchard, 2009).

Internet Defamation

The 'information superhighway' epitomized by the Internet exerts an enormous impact on defamation law all over the world. This is especially the case with jurisdiction and enforcement of defamation law. While other countries continue to sort out a vast array of jurisdictional and other related issues, the US Congress in 1996 passed a law immunizing Internet service providers (ISPs) from liability for third-party postings of defamatory material.

An oft-cited Internet defamation expert, Matthew Collins, noted the relevance of American law to other countries:

- (P)ersons in other common law countries are defamed by material written or edited in the Untied States, or hosted on the computer system of an Internet intermediary located in the Untied States;
- (S)uccessful claimants in foreign defamation actions seek to enforce their judgments in the Untied States, or where defendants apply to American courts to seek to prevent cases from proceeding in other countries or to have foreign defamation judgments declared unenforceable in the United States;
- (T)he American cases provide useful examples to illustrate the operation of the principles of defamation law discussed (in *The Law of Defamation and the Internet*);
- (T)he extent to which principles derived from the American Internet defamation cases might be capable of being adapted or applied in analogous circumstances in other common law countries cannot be assessed without an appreciation of the uniquely American approach toward, in particular, the elements of the cause of action for defamation, intermediary liability, jurisdiction over foreign publishers, and choice of law in multi-State defamation cases (Collins, 2010).

Transnational Defamation Litigation

As off-shore litigation against US and other transnational news media is growing, the globalizing media confronts a new type of defamation threat. The High Court of Australia's 2002 decision in *Dow Jones & Co. v. Gutnick* (2004) is a good illustration. Australian businessman Joseph Gutnick sued the American publisher of *Barron's* Online magazine in Australia for defamation. The Australian court held: When a defamatory statement is accessible to and read by ISP subscribers in an Australian state (Victoria in this case), a court of that state has jurisdiction to hear an action for defamation.

American courts have consistently refused to recognize and enforce foreign defamation judgments, holding that the judgments were based on defamation law repugnant to the US Constitution on press freedom. In 2010, in an effort to preempt various press freedom issues arising from 'defamation tourism' abroad, US President Barack Obama signed the SPEECH (Securing the Protection of our Enduring and Established Constitutional Heritage) Act, a federal law that bars the domestic enforcement of foreign defamation judgments against Americans if they are inconsistent with the First Amendment.

The gap between the United States and the rest of the world remains noticeable. But free speech defenses such as the American 'actual malice' (i.e., knowledge of falsity or reckless disregard for the truth) rule for the news media against liability for public defamation are increasingly accepted in other countries. For example, the UK Defamation Act 2013 and the Canadian Supreme Court have adopted 'public interest' and 'responsible communication,' respectively. This new media-friendly defamation defense precludes liability for responsible news reporting on a matter of public interest, although it resulted in false defamatory stories.

Privacy

Privacy never stops evolving as a dynamic value. It reflects keenly on how a society balances the 'right to be let alone' with its competing needs for information. Thus, it varies from society to society, which makes it challenging to generalize what privacy is as an individual right and why it should be so cross-culturally. Strikingly illustrative is the difference between Europe and the United States in weighing informational privacy against the freedom to publish.

In the United States, whose privacy tort law is one of the most highly developed and influential in the world, four types of invasion of privacy are recognized: intrusion, public

disclosure of private facts, false light, and appropriation. Especially, the 'private facts' tort is recognized widely, but its practical impact is severely limited by the First Amendment protection of the media's right to publish truth. News media are not liable for publicizing private facts if the disclosure is not highly offensive to a reasonable person and it is not a matter of public concern. American judges rarely second guess the media professionals' news judgments. Few American media organizations lose in private facts cases, although their stories have little to do with political expression on public issues.

The ECtHR could not be more different from American courts on the private facts tort. In 2004, for example, the ECtHR, ruling on a privacy complaint by Princess Caroline of Monaco, held:

> [A] fundamental distinction needs to be made between reporting facts – even controversial ones – capable of contributing to a debate in a democratic society relating to politicians in the exercise of their functions, for example, and reporting details of the private life of an individual who … as in this case, does not exercise official functions. While in the former case the press exercises its vital role of "watchdog" in a democracy by contributing to "impart[ing] information and ideas on matters of public interest … it does not do so in the latter case.
>
> (*Von Hannover v. Germany*, 2004)

When balancing freedom of the press with the right of privacy, the European Court has defined press freedom by focusing on the public's interest vs the public interest.

Access to Information and Free Press vs Fair Trial

The press's role of serving as a 'public watchdog' on the government and of imparting information on matters of public interest is difficult, if not impossible, to fulfill without access to public records. Without some protection for seeking out the news freedom of the press could be a farce. Now freedom of information (FOI) is accepted more widely around the world than ever. As of March 2014, a total of 100 countries recognized FOI as a right for the press and others. This is a profound development in freedom of the press as a positive concept. In this connection, it should come as no surprise that the Scandinavian countries that embrace a 'proactive' concept of press freedom have the most comprehensive FOI laws. For example, Sweden, whose government information statute is considered the oldest in the world, has adopted the policy on access to official records as a fundamental foundation of its democracy since 1766.

More importantly, the ECtHR in *Hungarian Civil Liberties Union v. Hungary* (2009) and the IACHR in *Claude Reyes v. Chile* (2006) have ruled that access to government information is a human right. Also, the Council of Europe has adopted an FOI treaty, the first of its kind in the world, and the United Nations Human Rights Committee has confirmed FOI as a fundamental human right.

Traditionally, freedom of the press in the United States has been confined to the right of news reporters and editors to disseminate any information in their possession, which does not necessarily extend to the legal right for the media to gather information. But newsgathering has now emerged as a vital issue for most journalists and news media organizations. In the United States, how to deal with access to government records, government agency meetings, and the like constitutes by far the largest body of mass media law.

Freedom of the press is often in conflict with the accused's right to a fair trial because news media wish to report on court proceedings as an important source of news information, while trials can be jeopardized by irresponsible news reporting. Meanwhile, cameras in the courtroom as a media right remain a contentious issue around the world. The US Supreme Court strictly prohibits television cameras. On the other hand, the Canadian Supreme Court has extensive experience with its hearings being broadcast. The Supreme Court of the United Kingdom is more camera-friendly than its US counterpart. The UK Supreme Court has allowed its hearings to be broadcast since its opening in October 2009 to replace the House of Lords. Brazil is one of the most open judicial systems when it comes to the broadcasting media's access to its highest court.

Journalist's Privilege to Shield News Sources

Equally important is the issue of whether journalists should be privileged to protect their confidential sources from forced disclosure. In the United States, a journalist's privilege is not recognized as such under the First Amendment. Indeed, it lags far behind Argentina, Japan, Norway, and Sweden, where journalistic privilege is the rule, not the exception.

The journalist's privilege has been read by the ECtHR into freedom of expression under the European Convention on Human Rights (*Goodwin v. United Kingdom*, 1996). More recently, the International Criminal Tribunal for the former Yugoslavia (ICTY) accepted the journalist's privilege as a right in international law. In endorsing the journalist's privilege, the ECtHR and the ICTY have embraced the watchdog press concept and the free flow of information notion, respectively.

Preventive Counseling for News Media

Because freedom of the press is litigated in increasing frequency in the United States, England, and other countries, media organizations involve lawyers in prebroadcasting and prepublication reviews. Lawyers in newsrooms have now become a fact of life for many, if not all, reporters and editors in dealing with a host of legal problems ranging from defamation to access to information. Some journalists are concerned about the chilling effect of lawyers' presence in and outside the American newsroom. Nonetheless, the journalist–lawyer relationship is not necessarily harmful to freedom of the press insofar as lawyers are sufficiently 'sensitive to the sometimes murky line between legal advice and journalistic or artistic judgment' (Smolla, 2014b).

No less important is the fact that journalists as the integral part of the media system are more often responsible than lawyers for determining what to broadcast or publish or what not to broadcast or publish. Likewise, a thoughtful UK study of the impact of defamation law on the media both in England

and in Scotland concluded "(A) solicitor's advice is just that and … on occasion editors do decide to ignore it" (Barendt et al., 1997).

Freedom of the US Press in the Globalizing Era

Freedom of speech and the press has been the international buzzword since the end of the Cold War in the late 1980s. The positive concept of press freedom has crystallized the undisputed paradigm throughout the world, and it inspires the standard for quality journalism. The growing impact of the modified libertarian press theory with an emphasis on the state's affirmative role in press freedom on Asia, former eastern Europe, and Latin Africa is credited partly to the American experiment of 200-plus years with a free press. At the end of his highly acclaimed book of 2010, *Uninhibited Robust and Wide-Open: A Free Press for a New Century*, meanwhile, Columbia University President Lee Bollinger, a leading First Amendment scholar, noted:

> This book has looked at the problem of what must be done for a global free press from a U.S. perspective. But we need to do this from the vantage point of other countries as well, especially those that generally share the same philosophy about the importance of a free and independent press. A collective effort toward the same end is a necessity.
> (Bollinger, 2010)

Freedom: Political

Timothy O'Hagan, University of East Anglia, Norwich, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Political liberty or freedom is an essentially contested concept, as Berlin emphasized. He distinguished positive liberty (the 'liberty of the ancients,' exercised in political participation, as well as in Kantian moral autonomy) from negative liberty (the 'liberty of the moderns,' the 'right to be let alone' in one's private life). That distinction has been refined, criticized, rejected, and resurrected in the subsequent debate. In the light of it, five rival approaches are distinguished within the English language literature. These are (1) welfare liberalism (Rawls and Dworkin), (2) libertarianism (Nozick), (3) freedom, economics, and power (the neo-Marxism of Cohen, the post-Marxism of van Parijs, and the neo-Aristotelianism of Sen), (4) freedom as attaining autonomy through community (Raz), and (5) civic republicanism, i.e., freedom as involving political activity (the instrumental version of Skinner; the constitutive version of Pettit).

Liberty, Equality, Fraternity, and Two Concepts of Liberty

Discussions of political freedom since the mid-twentieth century have rotated around two separate but related themes: on the one hand the slogan of the French Revolution 'liberty, equality, fraternity' and on the other hand Benjamin Constant's distinction between 'the liberty of the ancients and the liberty of the moderns,' transformed and transmitted to the English-speaking world by Isaiah Berlin in *Two Concepts of Liberty*.

Liberty, Equality, and Fraternity

Since the French and American Revolution modern states have been committed, at least formally, to the ideals of liberty, equality, and fraternity. However, from the start it became evident that those three aspirations are by no means automatically compatible. Attempts to balance them have taken different forms. Libertarian advocates of the *laissez-faire* market have argued that any attempt to promote greater equality of resources involves the illegitimate restriction of the right of individuals freely to pursue their own interests, whatever they may be. For some Marxists formal 'bourgeois' liberties are valueless until the inequality between social classes is abolished. Many others, who may be labeled social democrats in Europe or liberals in the United States, have sought to show that the three aspirations, far from being incompatible, are linked by ties of mutual entailment.

Two Concepts of Liberty

The most influential contribution to the topic of political freedom in the English language literature of the twentieth century remains Isaiah Berlin's *Two Concepts of Liberty*, delivered as an inaugural lecture at Oxford University in 1958. In it he distinguished 'positive liberty' (PL), exercised in political participation, as well as in Kantian moral autonomy, from 'negative liberty' (NL), the 'right to be let alone' in one's private life. The author made some changes to the later edition, but the core distinction remained intact. Berlin's lecture is an unsystematic mixture of different elements: conceptual analysis, political engagement in the postwar antitotalitarian struggle, and a rich, if eclectic, essay in intellectual history. But for all its shortcomings, it made the opposition between PL and NL central to much subsequent discussion.

Berlin's political task was to unmask the perversion of language by Stalinist ideologues, who presented the worst forms of oppression as 'real (socialist)' freedom, as opposed to 'mere bourgeois (formal)' freedom. Berlin aligned the former with 'positive' liberty and the latter with 'negative' liberty and reasserted the value of the latter against its critics.

Historically, Berlin identified NL with liberalism, the tradition that defended the individual against 'interference,' particularly when exercised by the state. However, the idea of 'interference' is hard to tie down. Berlin himself was ambivalent as to whether the interference must be deliberate or not, but he was adamant that an inability caused by the social structure (e.g., the inability of the worker to control the means of production in traditional Marxist theory) is not a case of unfreedom. He agreed that the 'classical English political theorists' were 'prepared to curtail freedom in the interests of other values and indeed of freedom itself.' They held that without law, 'freedom for the pike is death for the minnow.' A natural interpretation of that insight is that the law positively creates freedom for the minnow, allowing it to do things it would otherwise be unable to do. In the words of Locke (a quintessential negative libertarian for Berlin): "the end of Law is not to abolish or restrain, but to preserve and enlarge freedom." Berlin could agree that the pike's freedom is restricted for the sake of the minnow's freedom ('curtailed in the interests of liberty itself'), but his polemical drive was against partisans of PL who would maintain that the pike's freedom too is (really) enhanced by the restriction.

Another ambivalence within NL concerns the connection between freedom and wishes. Berlin began by tying the two together directly, defining oppression as "the part I believe to be played by other human beings … in frustrating my wishes." Later he rejected the definition of freedom as "the ability to do what one wants" because it is compatible with a situation in which all one's wants are restricted by brainwashing or the removal of desirable objects. At the heart of NL lies 'the right to be let alone,' but that right turns out to be remarkably elusive.

If NL is hard to tie down, PL is even more so. PL contains both (1) political elements (PL-pol) and (2) moral elements

(PL-mor). (1) is essentially the freedom to participate in the political process; (2) includes the ability to be the autonomous master of one's own drives, which is associated with the romantic notion of the divided self. Rousseau says that both (1) and (2) are the outcome of entering civil society, but he is careful not to identify them. When Constant (1988) introduced the distinction between the 'liberty of the ancients' and the 'liberty of the moderns,' he was concerned with (1). His polemical claim was that the 'liberty of the ancients' nowadays meant the unbridled exercise of popular sovereignty (PL-pol) to the detriment of NL. For Berlin, the danger of modern totalitarian ideology is that it harnesses (1) to (2). It suggests that, through laws endorsed by 'the people,' irrational empirical selves should be forced to coincide with rational ends (their 'real selves').

In response to the two themes identified earlier, five broad approaches to political freedom can now be distinguished. In each of these, the three fundamental values of liberty, equality, and fraternity are addressed. Writers inspired by Berlin focus on incompatibilities between those values. Others seek to show that when they are more clearly understood, it will be seen either that they are compatible or that the very idea of balancing one against the other must be abandoned. In their analyses, the terminology of PL and NL frequently recurs, but the distinction made above between dimensions (1) and (2) of PL frequently is ignored.

The approaches to be considered are (1) welfare liberalism; (2) libertarianism; (3) freedom, economics, and power; (4) freedom and community; and (5) civic republicanism.

Welfare Liberalism

For theorists of welfare liberalism, political freedom is exercised in a context of representative democracy constrained by constitutional checks to protect individual rights and by a fluctuating sense of obligation to redress the inequalities thrown up by the operation of the market. The two outstanding proponents of this approach are John Rawls and Ronald Dworkin.

Rawls

Rawls's *A Theory of Justice* (1971) is the most comprehensive, systematic work of modern political philosophy. In it the author expounds the moral basis of pluralist welfarism, combining the three elements of liberty, equality, and fraternity into a coherent whole.

At the heart of the book lie the two principles of justice. The first principle states that "Each person is to have an equal right to the most extensive total system of basic liberties compatible with a similar system of liberty for all." 'Basic liberties' are specified as "roughly speaking, political liberty (the right to vote and to be eligible for public office) together with freedom of speech and assembly; liberty of conscience and freedom of thought; freedom of the person along with the right to hold (personal) property; and freedom from arbitrary arrest and seizure as defined by the concept of the rule of law." These are what Marxists called 'bourgeois liberties.' The list is not equivalent to NL-pol, since they include certain 'positive' political elements, even if the 'negative' liberties of privacy may be more important than 'positive' ones to modern citizens.

In subsequent work, Rawls (1993) has responded to Hart's criticism that the idea of 'maximizing freedom' is incoherent. He has rewritten the first principle to read: "Each person has a claim to a fully adequate scheme of basic rights and liberties, which scheme is compatible with the same scheme for all; and in this scheme the equal political liberties, and only those liberties, are to be guaranteed their fair value." He has also added the 'integrity' (physical and psychological security) of the person to the list of basic liberties to be protected by the first principle. However, he has not modified the central claims of *A Theory of Justice* that the modern liberal state must (1) guarantee 'basic liberties' and (2) strive to maximize the welfare of the worst-off members of society by redistributive mechanisms, and that the first principle must not be sacrificed to the second, since 'liberty can be restricted only for the sake of liberty.'

Most of the other important revisions have concerned structure and methodology rather than content. Rawls has anchored the two principles more explicitly in a conception of citizens of a modern pluralist state, as it has developed since the Reformation. They are 'regarded as free and equal persons,' endowed with "two moral powers … namely a capacity for a sense of justice and a capacity for a conception of the good." Such citizens display their freedom in the following ways. They have 'the moral power to have a conception of the good' and are 'capable of revising and changing this conception.' They 'regard themselves as self-authenticating sources of moral claims.' They are capable of taking responsibility for their 'ends.'

The two principles of justice remain unaltered and are still subject to attack from both left and right. Left-wing critics charge that first principle 'bourgeois' liberties are hollow and worthless for the mass of the population. To them Rawls had already responded in *A Theory of Justice* by distinguishing equal liberty from equal worth of liberty, acknowledging that it is the latter that is important, and predicting, perhaps optimistically, that it would be enhanced by the application of the difference principle. Right-wing 'libertarian' critics reject all redistributive mechanisms, because they infringe the individual's unrestricted right to accumulate property. Rawls' response to them is also contained in *A Theory of Justice*, namely, that individuals have a basic right to own personal property, but that right does not entail any particular property system, whether capitalist or socialist. In each particular case the choice of system will be determined by its ability to maximize the welfare of the worst-off.

Dworkin

Dworkin's political philosophy is an attempt to 'fine-tune' both the methodology and the political recommendations of Rawls's welfare liberalism. Methodologically, Dworkin denies that liberalism must balance liberty against equality. That image wrongly presupposes that liberty can be quantified, so that 'fundamental' liberties weigh more heavily than trivial ones. Instead, 'the fundamental liberties are important because we value something else that they protect.' That 'something else' is, unexpectedly, a form of equality, the principle that a government should treat all its citizens with 'equal concern and respect.' The 'fundamental' liberties, then, are entailed by the equality principle itself, according to which 'the government (should) treat all its citizens as free, or as independent, or with equal dignity.' Dworkin accepts the Rawlsian requirement that "political decisions must be … independent of any particular conception of the good life …." Thus governments are bound by the negative requirement to be neutral between

lifestyles, and also by the positive requirement to 'respect' the 'dignity and independence' of its citizens.

In terms of political recommendations, Dworkin proceeds from a tension at the heart of Rawls's two principles. While the first principle defends the conditions of basic freedoms, and addresses people as autonomous agents, the second principle might undermine people's motivation to exercise their freedom to 'better themselves,' addressing them as passive recipients of benefits. In response to this tension, Dworkin introduces a key modification. He follows Rawls in compensating people for 'irrelevant differences, like differences in talent.' However, he argues that people should be 'responsible for the costs of their choices.' The system, in short, must be both 'ambition sensitive' and 'endowment insensitive.' However, Dworkin's modification may have introduced a new tension of its own, since, however finely tuned it is, its two requirements must work against one another: "the more we try to make the distribution sensitive to people's ambitions, the more likely it is that some people disadvantaged by circumstances will be undeservedly penalized, and vice versa" (Guest, 1997). Everything now hinges on the possibility of making a realistic distinction between ambition and endowment, between 'personality' and 'circumstances.' The fact that this is so difficult suggests that the tension between freedom and equality may still be unresolved.

Libertarianism, Freedom as the Unrestricted Right to Own Private Property: Nozick

Nozick's *Anarchy, State and Utopia* (1974) was a polemical response to Rawls' *A Theory of Justice*. At the time of its publication, there was a backlash against welfarism and state intervention in the economy. That backlash was driven by the economic theory that managed markets are inefficient, since redistribution through taxation takes away incentives. However, although Nozick's book was congenial to that theory, his philosophical position is independent of it. Nozick would defend his position on the grounds that it was the correct one, even if it were inefficient. He would in fact reject appeals to economic efficiency as improperly utilitarian.

Although labeled a 'libertarian,' Nozick's starting point is not the idea of 'liberty' or 'freedom,' but rather the Lockean one of 'self-ownership.' This has polemical value because it allows Nozick to proceed against Rawls' (and other welfarists') programs of redistribution by appealing to a hatred of slavery shared by all across the political spectrum since the 'bourgeois revolutions,' and suggesting, by a rhetorical sleight of hand, that "taxation of earnings from labor is on a par with forced labor." The slide has some source in Locke's 'labor theory of property,' the idea that one has a property right to something if one has 'mixed one's labor with it.' However, Locke did not suggest that that right is absolute in the same sense that one's right to bodily integrity is.

The sleight of hand at the heart of libertarianism is this. We all agree that if A has the right to make use of B's body, of which B is the rightful owner, without B's consent, then B is A's slave. By parity of reason, it is suggested, if A has the right to make use of B's property, of which B is the rightful owner, without B's consent, by taxing B, then B is A's slave. The sleight of hand depends on accepting the extension of self-ownership from ownership of one's own body to ownership of whatever one has acquired legally, an extension that is not evidently justified. Nonetheless, libertarians may be able to deploy a 'slippery slope' argument against welfarism without making this particular sleight of hand. Rawls's two principles of justice are intended 'to balance the twin demands of (1) respecting choices and (2) rectifying circumstances.' Rawls intends (1) to be applied to individuals, (2) to groups. However, according to the libertarian, there is nothing within Rawls's theory to prevent the radical welfarist from extending rectificatory treatment to individuals too. How is one to define what intervention is legitimate in order to rectify circumstances? If the line is to be drawn around the body, it would seem to mean that any nonbodily interference is at least in principle legitimate in order to rectify circumstances. That sounds sinister even to those who are not extreme 'libertarians.'

Freedom, Economics, and Power

In the past, egalitarians, Marxists, and non-Marxists alike derided 'bourgeois freedoms' for masking from the workers their real enslavement. The modern egalitarians considered in this section all take seriously the demand for real equality of freedom. However, unlike their predecessors, they all also take seriously the importance of the 'basic' freedoms that lie at the heart of liberalism. The three positions considered in this section are linked by the insight that freedom and equality are linked intimately, and that the conditions of equality and inequality are zero-sum relations of economic power. In each of the three, real freedom is 'positive' in the sense that it requires more than just the 'right to be let alone.' On the other hand, it is not the 'liberty of the ancients,' since it recognizes the importance of private life in the modern world.

Neo-Marxism: Cohen

In the most sophisticated version of neo-Marxism, that of Cohen, "there is … a conflict between social equality and the liberty of some people," but that should not stand in the way of "the pursuit of social equality, since a humane concern for liberty must first of all direct itself to the condition of those who enjoy hardly any of it."

Neo-Marxists thus agree with liberals that freedom of the individual is the most important political value, and that modern capitalism delivers it to all members of society, including proletarians, in several important ways. First, all members of a capitalist society (worker and capitalist alike) are legally free. Second, any particular worker is always legally free, and often economically free, to leave the proletariat and become a petty bourgeois or even a capitalist. However, within a capitalist society, 'although most proletarians are free to escape the proletariat, indeed even if all are, the proletariat is an imprisoned class.' Third, capitalism has delivered 'important freedoms beyond that of buying and selling.' These include 'freedom of speech, assembly, worship, publication, movement, and political participation.' The neo-Marxist Cohen is agnostic about 'how accidental the connection between capitalism and those freedoms has been and is,' but is committed to the view that only 'freedom to buy and sell belongs to

capitalism's inmost nature.' However, Marxists must still acknowledge that 'bourgeois freedoms' really are freedoms: "… when socialists suggest that there is no real liberty under capitalism, or that socialism promises liberty of a higher and unprecedented kind … their line is theoretically incorrect and politically disastrous. For liberty under capitalism is, where it exists, just that, liberty; and if socialism will not give us plenty of it, we shall rightly be disappointed."

In recent writings, Cohen (1995) has begun to investigate the idea of real freedom, understood as 'autonomy, the circumstances of genuine control over one's own life.' With this turn, neo-Marxism returns to the old site of conflict, since we must 'ask what kind and degree of control over external things a person must have to enjoy autonomy, and then to ask whether such control is compatible with socialist equality.' Cohen's project now is to translate the idea of real freedom into terms that are applicable to the real world, and, where possible, quantifiable. His model of 'equal access to advantage' now stands alongside Van Parijs's (1995) and Sen's (1992) models. It thus forms part of a rich developing research program. Whether it should still be called Marxist is another question.

Post-Marxism: van Parijs

In the post-Marxist program of van Parijs, the normative goal of equalizing access to freedom is maintained. At the same time, the Marxian theory of exploitation is abandoned, and the capitalist market is now seen as the only vehicle that can deliver 'real freedom for all' in practice. The goal is to 'empower' the greatest number of people. The method is to guarantee them an unconditional 'basic income' that will prevent personal dependence and allow individuals to make meaningful choices between life styles. The 'basic income' project has now entered the real political agenda in Western Europe.

The goal of the post-Marxists is to reconcile freedom and equality by the principle to 'maximization of an unconditional income, subject to formal freedom being protected and to no one's endowment being unanimously found worse than someone else's.' That would guarantee the widest, and fairest, distribution of 'real' freedom that could also be delivered by a 'sustainable' economic system. Van Parijs maintains that that system would be a highly regulated, interventionist form of capitalism. His reasons are fourfold. First, it is (probably) more efficient than socialism. Second, it can (probably) guarantee a higher basic income than socialism can. Third, it can (certainly) guarantee formal freedoms, whereas socialist régimes have still to prove that they can. Last, and this is a decisive consideration, even if there are reforms of international economic affairs, it will be impossible to promote an 'autarkic' socialist régime in one country without imposing unacceptable restrictions on the movement of its people to other (higher paying) countries.

Neo-Aristotelian Freedom as Capability: Sen

The third egalitarian model combines sophisticated economic theory with a deep philosophical anthropology derived from Aristotle. The leading proponent of this model is Sen.

The aim here is to construct a model of freedom that is sufficiently objective to be used in cross-cultural comparisons, but that is also sensitive to the different weightings given to the elements of a flourishing life in different cultures. Sen (1992) draws up a list of 'functionings' that include 'being adequately nourished' and 'having self-respect,' and defines 'well-being freedom' as the capability to achieve those functionings. However, there is also 'agency freedom,' defined as the capability to achieve whatever one's objectives are. Since many people have objectives other than their own well-being, these two freedoms may conflict.

It is agency freedom that has been at the center of most liberal discussions. Sen acknowledges its importance, but weighs it alongside well-being freedom in evaluating the totality of a person's life. Even within agency freedom, Sen advises liberals not to exaggerate the importance of the agent's direct control of an outcome. Instead, he proposes a counterfactual formula, "I am free when control is exercised in line with what I would choose." That formula can be generalized to cover all forms of freedom, even when the term 'freedom' is extended to cover 'freedom from hunger,' 'freedom from malaria,' etc.: 'One values living without malaria, desires such a life, and would have chosen it, given the choice.'

Society has different obligations to its members concerning their well-being and their agency. It has an evident 'responsibility to a person's well-being, especially when it is in some danger of being particularly low,' which it does not have for that person's particular agency objectives. In advanced liberal societies at least, 'in which the focus is on the freedom that people have,' no patterned outcome can be imposed. For 'even when complete equality of well-being freedom is … entirely realized, this need not lead to an equality of well-being achieved, since different individuals may give different priority to the pursuit of their own well-being.' In rejecting patterned outcomes, Sen has shown that the capability model does not conflict with the central values of liberalism expounded by Rawls and Dworkin.

The capability model inherits from Aristotle the idea that human beings are endowed with specific capacities that can be more or less fully realized in a flourishing life. In his presentation of the model, Sen is concerned that Aristotle's particular 'view of human nature (with a unique list of functionings for a good human life) may be tremendously overspecified.' He prefers to leave open 'both … the exact grounds underlying the determination of relative weights, and the actual relative weights chosen.' This gives Sen's version of the 'capability approach' not only a degree of incompleteness relative to Aristotle's but also, he thinks, a "considerable 'cutting power'" for use in the real world of cultural diversity.

Freedom as Attaining Autonomy through Community: Raz

Communitarian critics including Taylor, MacIntyre, and Sandel brought two charges against liberalism. At the level of theory, they claimed that it is based on a methodological individualism that in turn derives from an impoverished, atomistic conception of human nature. At the level of practice, they argued that because the liberal order fails to provide a satisfactory sense of identity for its members, 'intolerance flourishes most where forms of life are dislocated, roots unsettled, and traditions undone.'

Along with the communitarians, Raz (1986) rejects methodological individualism, but against them he argues that this

does not entail a rejection of liberal values. Raz's liberalism, 'the doctrine of limited government,' is rooted in a 'non-individualist conception of morality.' In opposition to Rawls's antifoundationalism, Raz propounds a "doctrine of political authority that rests on a perfectionist political defense and promotion of liberty and autonomy." However, this is not a brutish libertarianism, since freedom is 'a distinct value, but one that is intimately intertwined with others, and cannot exist by itself.' Raz in short is a foundationalist, who seeks to establish 'continuity' between a moral base and a political–legal superstructure.

For someone to attain 'the ideal of autonomy' and live an autonomous life, certain conditions must be satisfied. These are the possession of 'appropriate mental abilities,' of an 'adequate range of options,' and of 'independence.' The ideal is positive and comprehensive. It constitutes the moral base of the system, but is not 'moralistic.' In particular, it does not involve a teleological conception of self-realization, since, as an autonomous person, one is free to choose whether or not to realize oneself. However, without teleology it is difficult to make autonomy foundational. If autonomy involves integrity ('identification with one's life'), self-awareness and commitment to a project, it can still be asked why it is valuable. It is insufficient to answer that 'many people desire to be autonomous,' since people's desires are many, conflicting, and mutable. Rather, says Raz, "the value of autonomy does not depend on choice … the conditions of autonomy concern a central aspect of a whole system of values of a society …." The kind of society in question is a pluralistic society, which both supports and is supported by this central value 'valuing autonomy leads to the endorsement of moral pluralism.'

Other modern liberals, notably Rawls, are cautious about seeking to found political legitimacy on a particular understanding of freedom. They hold that particular individuals and groups can value freedom for different reasons, some welcoming it because it is a purely negative guarantee against interference, others because it embodies their highest aspirations. Against them Raz holds that most people in a liberal state must subscribe to the positive value of freedom as autonomy, otherwise its tolerant pluralism will perish.

Civic Republicanism

In the fifth model of political freedom, the 'liberty of the ancients' reenters the modern debate. In both versions of 'civic republicanism' considered below, political participation plays a key role, a purely instrumental role in the first, and a constitutive role in the second.

The Instrumental Notion of Civic Republicanism: Skinner

Skinner's model, known variously as 'civic republicanism,' 'classical republicanism,' and 'neo-Romanism' is rooted in the Renaissance, in particular in the idea derived from Machiavelli that a state that is 'free from all external slavery' guarantees 'personal liberty, understood in the ordinary sense … each citizen remains free from any elements of constraint, especially those that arise from personal dependence and servitude, free to pursue his own chosen ends … To be free … is simply to be unconstrained from pursuing whatever goals we may happen to set ourselves.' The independence of the state is linked to the freedom of the individual insofar as 'a self-governing republic is the only type of régime under which a community can hope to attain greatness at the same time as guaranteeing its citizens their individual liberty.' Such a state requires two capacities or virtues from it citizens, courage and determination to defend their community against external attack, and practical reason that qualifies them to play an active part in public life. This means that the state can, legitimately, force the citizen to be free. Despite appearances, this 'strenuous view of citizenship' is, according to Skinner (1990), consistent with NL in two respects. First, it does not presuppose any specific teleological theory of human nature. Second, when we are 'forced to be free,' we are being forced not to 'reason about ends,' but to 'recognize the range of actions we have good reason to perform in order to bring about the ends we actually desire.' Skinner illustrates the latter point by a contrast between 'liberals' like Hobbes and Locke on the one hand and Machiavelli on the other. The 'liberals' assert only that the law preserves A's freedom by coercing B (the potential law-breaker). Machiavelli asserts this. But also asserts that the law also preserves A's freedom by coercing A "into acting in a particular way … forcing us out of our habitual patterns of self-interested behavior … into discharging the full range of our civic duties and thereby ensuring that the free state on which our own liberty depends is itself maintained free of servitude." In short, because "freedom depends on service and so on our willingness to cultivate the civic virtues … we may have to be coerced into virtue and thereby constrained into upholding a liberty that, left to ourselves, we would have undermined." Skinner comments that "contemporary liberalism … is in danger of sweeping the public arena bare of any concepts save self-interest and individual rights." Ideologies suspicious of the whole modern agenda of individual freedom have stepped in to fill that vacuum. Skinner (1998) thinks that 'republican freedom' provides a robust defense against such reactionary positions.

The Constitutive Notion of Civic Republicanism: Pettit

In the second version of civic republicanism, espoused by Pettit (1997), Berlin's dichotomy of the positive freedom of self-mastery and the negative freedom of noninterference is not exhaustive. Beyond those two lies republican freedom, which means absence of domination, not absence of interference. Domination differs from interference in important respects. Domination is a function of the relationship of unequal power between persons or groups of persons. It relates to the capacity of one person or group of persons to interfere in the choices of other persons or groups, rather than to actual instances of interference. However, that would not be enough to pick out the undesirable character of domination, since any non-anarchist social order will empower certain persons or groups, giving them authority over others in given circumstances. So domination is not just the possession of power, but the possession of arbitrary power. The goal of republican freedom, then, is that 'no one is able to interfere on an arbitrary basis – at their pleasure – in the choices of the free person.' With this formula Pettit seeks to extract the rational kernel of both negative and positive freedom, while showing that neither is

sufficient in itself. On the one hand, freedom as non-domination 'will facilitate the achievement of autonomy,' as positive freedom requires. On the other hand, it will respect people's empirical choices, as negative freedom requires, but it will go beyond by showing that dominated people are not really free even if they have the good fortune to suffer no interference when their dominators choose to refrain from exercising their arbitrary power.

Insofar as republican freedom is tied to power, it is essentially egalitarian. It is held to protect each individual against arbitrary power, and also to be a 'communitarian good,' allowing people to identify with a state that protects their freedom. This version of republican freedom is heavily influenced by Rousseau, purged of totalitarian accretions, and updated to the advanced capitalist societies of the late twentieth century. They are now explicitly inclusive, bestowing their benefits on all members of society, and also multicultural, displaying liberal neutrality toward different substantive conceptions of the good. How far such societies can provide a stable balance between the participatory core of republican freedom and the centrifugal drives of modern pluralism remains to be seen.

Free Will and Action

Abstract

When agents are in circumstances that do not constrain their choices in any way they enjoy *freedom of action*. They are able to do whatever they want to. However freedom of action, so understood, is neither necessary nor sufficient for moral responsibility. It is not sufficient because, at least when placed in suitably unconstraining circumstances, spiders, mice, infants, and the like, all enjoy freedom of action, but they are not morally responsible for anything that they do. It is not necessary because people who falsely believe that they enjoy freedom of action may be morally responsible. What is both necessary and sufficient for moral responsibility is *freedom of the will*. Agents enjoy freedom of the will when they possess a dual capacity. On the one hand, they must have the capacity to form well-justified beliefs about what they have reason to do. On the other hand, they must have self-control: the capacity to bring their desires in line with their reflectively formed beliefs about their reasons. Many urge that moral responsibility is impossible in a deterministic world. But whether or not this is so depends on whether rational capacities, quite generally, are possible in a deterministic world. It is a question for further investigation whether this is so.

According to the standard account of action, an agent's acts are those of his bodily movements that spring in an appropriate way from his will. Bodily movements that are caused in some other way – the bodily movement of someone who gets blown over by the wind, say – are not among the actions agents perform. More precisely, an agent's actions are those of his bodily movements that occur because he wills them to, where an agent's will is, in turn, identified with his desires and means-end beliefs: actions are bodily movements that occur because an agent desires some outcome and believes that that outcome can be produced by his moving his body in the relevant way, a way he can move it. Bodily movements that trace their causal history to other states or events in an agent's psychology, or to nonpsychological states or events are not actions (Davidson, 1963).

The standard account of action suggests that all animals that are capable of desire and belief, whether those animals are human or nonhuman, are capable of action. The bodily movement of a mouse occurs because the mouse wants some cheese and believes that it can get some by running in the direction of the crumbs on the floor is an action of the mouse, just as much as the intricate performance of a gymnast or a ballet dancer. By contrast, the movement that the mouse makes when it is picked up by a cat and flung across the room is not an action, any more than the movement of a ballet dancer who is unceremoniously dropped to the floor by her partner.

Not all of an agent's actions, whether the agent is human or nonhuman, are free, however, notwithstanding the fact that they all spring from his will. When a mouse is caught in a trap by its tail, it may give up the struggle and sit down near the trap. Its body remains under its control, not under the control of some alien force, but staying near the trap is not something that the mouse does freely. Similarly, when a person is locked in a prison cell the individual may give up the struggle and sit on the chair behind bars. But staying behind bars is not something that the individual does freely. What, then, within the class of actions, is the mark of those of an agent's actions that are free, as opposed to those that are unfree?

Everyone agrees that free actions are those that are under the agent's control, and some suggest that this means free actions are all and only those that are done intentionally: that is, they are those of an agent's actions which, suitably described, can be seen to have been rationalized by the individual's desires and beliefs (Davidson, 1973). This idea might seem supported by paradigm cases of unfree action, such as that of the human and the mouse. For although the mouse stays near the trap and the human stays behind bars, neither does what they do intentionally under these descriptions. The human, for example, intentionally sits on a chair, as opposed to sitting on the ground – that is something that is rationalized by the individual's desires and beliefs – and one consequence of thus sitting on the chair is that the individual stays behind bars. But the individual does not have any desires and beliefs that rationalize the individual's staying behind bars. That is merely a consequence of what the individual does intentionally, not itself something that the individual does intentionally.

But though this certainly captures one sense in which we might say of actions that they are under an agent's control, it does not capture all there is to the idea. It entails, for example, that whenever someone who acts in a certain way knowingly, but not intentionally, he does not act freely, and this is surely quite wrong. Suppose that someone, A, desires to convey to another, B, the low opinion he or she has of a third person, C. But let us suppose further that he or she goes on to tell B in full knowledge of the fact that C is standing within earshot, and so causes C to become embarrassed. A could have waited until C left, but did not because A did not care. A then knowingly causes C embarrassment, but A does not do so intentionally, as there is no desire of A's such that A believes he or she can satisfy that desire by embarrassing C. C's embarrassment is merely a foreseen consequence of what A does do intentionally, which is to tell B his or her low opinion of C. It would, however, be extremely implausible to suppose that the fact that C's embarrassment was merely foreseen, rather than intentionally produced, makes it the case that A did not cause C's embarrassment freely. It was, after all, entirely up to A whether or not

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63026-X

C would be embarrassed by what A said to B about C. A was not forced to embarrass C. Embarrassing C or desisting from doing so was under A's control.

Or suppose that someone, D, desires to convey to another, B, the low opinion he has of a third person, C. But this time let us suppose that, eventhough D does not know that C is standing within earshot, in view of the fact that C is nearby where D and B are, D could have ascertained the fact that C was in close proximity, and then waited until C left, but D did not do so because D did not care enough. In this case, D both unintentionally and unknowingly causes C to become embarrassed; D has neither any specific desire or satisfaction by embarrassing C, nor does D even foresee that he or she is embarrassing C. C's embarrassment is in this case a negligently unforeseen consequence of what D does do intentionally, which is to tell B his or her low opinion of C. It would, however, once again be implausible to suppose that the fact that C's embarrassment was neither intentional nor foreseen makes it the case that A did not cause C's embarrassment freely. It was, after all, entirely up to A whether or not C would be embarrassed by what he said. He was not forced to embarrass C. He could easily have availed himself of C's presence. Embarrassing C (or desisting from doing so) was therefore under A's control.

The more standard idea has thus been that an agent's acts are free just in case they are under the agent's control in the more mundane sense that the agent could have done otherwise than what he in fact did when the agent acted (Wiggins, 1973). The question 'Did the agent act freely?' is in this way supposed to reduce to the question 'Did the agent have any alternative option?' A's causing C to become embarrassed is therefore indeed a free action, on this way of seeing things, because A had the option of acting in some other way instead. He could have waited until C was out of earshot. This is the relevant sense in which free actions are under an agent's control. The reason that a mouse caught in a trap does not stay in the vicinity of the trap freely is thus that it has no other option: it cannot do otherwise but stay near the trap. And the reason a prisoner who sits on a chair in a locked prison cell does not stay behind bars freely is that this individual, too, has no other option: the individual cannot do otherwise than stay behind bars.

However this more standard account of free action immediately raises a difficult issue, for without a special explanation of what the 'could' means, it seems to imply that freedom of action is impossible in a deterministic world. Every action performed by an agent in a deterministic world is fixed by the way the world was long before the agent was born together with the operation of causal laws. In a very familiar sense of 'can,' no agent can ever do otherwise than he in fact does. Agents are therefore always forced to do what they do by their past and the forces of nature.

Incompatibilists – those who think that freedom is impossible in a deterministic world – happily accept this conclusion (van Inwagen, 1975). But they in turn divide over the substantive question whether the world is or is not deterministic. Those who think that it is – the so called 'hard' determinists – draw the conclusion that there are no free actions. Those who think that there are free actions – the 'libertarians' – draw the conclusion that the world is not deterministic. But not everyone is an incompatibilist. Compatibilists find it difficult to see how the mere fact of causal determinism is supposed to undermine freedom of action. If anything, they insist, things are the other way around. Events that cannot be explained causally are completely random: that is what it means to say that an event eludes causal explanation. But free actions can hardly be randomly produced. Free actions, like all actions, are produced in a very reliable fashion by the desires and beliefs of their agents. They therefore conclude that free actions, if there are any, are caused by desires and beliefs, and hence the sense of 'could' at issue must be different from the one that so impresses the incompatibilists (Ayer, 1954).

Compatibilists have therefore coupled the suggestion that an agent's acts are free just in case he could have done otherwise with a special explanation of what this 'could' means. To say of an agent that he could have acted otherwise, in the sense relevant to establish freedom of action is, they suggest – or, at any rate, this is the way the suggestion was originally put – to say of him that he would have done otherwise if he had chosen to (Moore, 1911). In other words, freedom of action turns on whether or not, in the nearby possible worlds in which agents choose to do otherwise than they do in actuality – these are possible worlds in which the past is ever so slightly different – they succeed in doing what they choose to do. The truth or falsity of determinism is irrelevant.

The intuitive idea here should be clear enough, for the suggestion amounts to the claim that agents enjoys freedom of action if the external world presents no barrier to their efforts to act as they will: freedom is a matter of the absence of such external barriers or constraints. To see how this allows us to sort cases of free from cases of unfree action, consider the difference between two men who stay in a prison cell, one of whom is locked in, and one of whom is not. The difference is that the one, but not the other, would have walked out of his prison cell if he had chosen to do so: in the nearby possible worlds in which the agent who is locked in his prison cell chooses to walk out, he fails to do so, as he is still locked in, whereas in the nearby possible worlds in which the agent who is not locked in his prison cell chooses to walk out, he succeeds in doing so, as his cell presents no barrier to him. The one has the option to walk out, whereas the other does not. Moreover this account is, apparently, fully general. Of two mice that stay nearby a trap, the one whose tail is not caught in the trap, and so moves away in the nearby possible worlds in which it chooses to do so, stays nearby the trap freely, whereas the one whose tail is caught in the trap, and so does not move away from the trap in the nearby possible worlds in which it chooses to do so, does not stay nearby the trap freely. The external world presents a barrier to the movements of the latter, it serves as a constraint, but it presents no such barrier or constraint to those of the former.

Intuitive though this idea might be, however, the suggestion in the form in which it was originally made is problematic. The problem is that, since choosing is itself an action, it is something that people can do freely or unfreely (Chisholm, 1964). But now suppose we ask whether a particular action is free. This turns on whether the agent could have done otherwise than what he in fact did, and, according to the suggested analysis of 'could,' this turns on what happens in those nearby possible worlds in which the agent chooses to act otherwise. But whatever answer we give to this question, we have been forced

to admit that the status of the original action as free or unfree turns on what happens when another merely possible act is performed, an act whose status as free or unfree is left up in the air. Moreover the status of this merely possible act turns on whether or not, in those nearby possible worlds in which the agent chooses otherwise than to choose to act otherwise, he succeeds in so choosing. And, whatever answer we give to this question, it follows that we have therefore been forced to concede the possibility of yet another act whose status as free or unfree needs to be determined. And so we must go on.

The problem is thus that in order to raise and answer any particular question about the freedom of an action we are required to posit further acts of choosing to act otherwise, and choosing otherwise than to choose to act otherwise, and so on, about which we can raise the question whether they are free or unfree. The problem is not just that questions about freedom of action are never answered, once and for all – every question answered leaves another posed but unanswered, and so on *ad infinitum* – the problem is rather that it is implausible to suppose that every being capable of free action is capable of such ever higher and higher order acts of choosing. In order to raise the mundane question whether a mouse, caught in a trap, sits nearby the trap freely or unfreely it is surely quite incredible to suppose that we must thereby concede the possibility of its choosing to do otherwise than to sit near the trap, and choosing otherwise than to choose to do otherwise than to sit near the trap, and so on. Mice simply are not cognitively sophisticated enough to make such choices.

How are we to solve this problem? The suggested analysis of 'could have done otherwise' clearly needs to be rephrased so that the possibility of the freedom of an agent's actions does not entail the possibility of his making ever higher and higher order acts of choice. We should therefore suppose that for it to be true that an agent could have done otherwise it has to be the case that he would have done otherwise, not if he had chosen, but rather *if he had wanted*. This not only removes the problem we have just encountered – it is indeed possible for agents whose acts are free, humans and mice alike, to want other than they actually want, and that possibility does not commit us to the possibility of their making higher order acts of choice – it also better captures the intuitive idea presented at the outset, the idea that an agent's actions are free to the extent that they are dependent on his will. For, as we saw, an agent's will is to be identified with his wants and means-end beliefs. To say of an agent, be he human or mouse, that the agent acts freely is thus, according to the rephrased suggestion, to say of him that, in the nearby possible worlds in which he wants something different, he acts in that different way. This is what it is for him to have alternative options.

Note two consequences of this account of free action. The first is that certain acts which we would have ordinarily supposed to be unfree are not really unfree. When someone says 'Your money or your life!' and I give him my money, we would ordinarily say that I do not act freely because I have been forced to hand over my money. But, according to the account on offer, I do act freely. I have another option: I refuse in those nearby possible worlds in which I want not to give him my money more than I want him not to kill me. Many think that this is implausible. They insist that there must be a sense in which my freedom is compromised by such a threat, as even though I refuse in the nearby possible worlds in which I want to refuse, wanting to refuse would not be at all reasonable, in those circumstances. Indeed, not only would it not be reasonable, it would be completely crazy. There is, they suggest, thus the following sense in which the person who threatens me forces me to act: he puts me in circumstances in which there is no other reasonable option but to comply with his threat. But if this is right – that is, if this is the sense in which threats compromise my freedom – then it seems to follow that people who make me irresistible offers equally compromise my freedom, for they too put me in circumstances in which the only reasonable option is to accept their offer. Whether it is acceptable to suppose that the only sense in which threats compromise my freedom is a sense in which offers also compromise my freedom clearly needs much more thought (Frankfurt, 1973).

The second consequence concerns the relationship between free action and moral responsibility. According to this account of free action, freedom is not sufficient for an allocation of moral responsibility. Mice often act freely, but they are not morally responsible for any of their acts. Something else is therefore required. Other more complicated cases tell in favor of the same conclusion. Consider, for example, the plight of a reluctant alcoholic who wants to have a drink, and so has one, knowing he should not. He presumably drinks freely, as he does not drink in those nearby possible worlds in which he wants not to have a drink. Yet it is surely an open question whether or not he is morally responsible for his drinking. If, for example, his desire to drink is literally irresistible, then he is not responsible. Indeed, we would even think that he is not free, in the important sense of being unable, in the circumstances, to want to do anything else except to drink. This more complicated case thus suggests that in order to understand the conditions of moral responsibility we must look not so much to an account of free action, but rather to an account of freedom of the will. The idea is that, though the alcoholic's actions may be free, his will is not, and that this is therefore the source of our judgments about moral responsibility (Frankfurt, 1971).

Is the performance of a free action a necessary condition of moral responsibility? The answer seems to be that we can and do hold agents responsible for acting when they have no alternative, and that acting freely would thus seem not to be a necessary condition either. Those who act in the false belief that their acts are free are often held morally responsible for what they do, notwithstanding the fact that they don't act freely. Imagine, for example, that when a family visits an old prison they disperse so that they can explore the place individually, but that they agree to meet at a certain time to go home. When the agreed time to leave arrives, suppose that one of the children fails to turn up. His parents look for him and find him in a cell. Because he does not want to leave, he has hidden from them. But now suppose that the cell door is closed, and that, unbeknown to the child, it is not just closed but also locked. It then follows that the child had no alternative but to be in the prison cell when it came time to leave. He could not have met the rest of his family. Is the child off the hook in terms of responsibility? Hardly. His parents would surely quite rightly continue to hold him morally responsible for failing to turn up. The fact that he could not have done otherwise is

irrelevant because it does not figure, in the right kind of way, in the explanation of the child's failure to meet them. In order to see what is relevant, though, we must once again look at what does figure. This case, too, suggests that we need to look more carefully to an account of freedom of the will (Frankfurt, 1969).

It might be thought that we should simply model our account of freedom of the will on the account we give of freedom of action. Just as freedom of action is a matter of being in circumstances in which one can do whatever one wants to do, it might be thought that freedom of the will is a matter of being in circumstances in which one can want whatever one wants to want (Frankfurt, 1971). Where freedom of action is a matter of the absence of external constraints on action, so freedom of the will is a matter of the absence of internal constraints on wanting. An agent's will is free just in case, in those nearby possible worlds in which he wants to want to act in a certain way, he wants to act in that way.

There is clearly something right about this idea. Those who enjoy freedom of the will do seem to have the capacity to control their will, where this includes the capacity to control their first order desires. The problem with the reluctant alcoholic seems to be that he has no such ability: his desire to drink is beyond his control. What is less clear, however, is that this idea is well captured by the suggestion just made. The desires an agent has about his first order desires are, after all, just more desires he has, and are hence just another part of his will, a part which may or may not be under his control (Watson, 1975). Thus, even supposing it to be true that in those nearby possible worlds in which an agent wants to want to act otherwise, he wants to act otherwise, we can always imagine that the agent is unable to have wanted to want to act otherwise. And if the agents were unable to want to act otherwise then we must surely ask in what sense he enjoys freedom of the will. Certain of the desires such an agent has in certain possible worlds are controlled by certain others in those worlds, but the agent himself does not seem to be in control of any desires at all.

Some theorists have argued that in order to solve this problem we need to postulate a special kind of higher order desire: a desire which captures the agent's own sense of his identity (Frankfurt, 1987). When an agent has this sort of higher order desire, they suggest, he identifies himself with the lower order desires that are this higher order desire's objects. Freedom of an agent's will is, the suggestion goes, a matter of his being able to have desires that match this sort of higher-order desire: in other words, it is a matter of having desires with which he identifies.

The difficulty with this suggestion, however, is to come up with a suitably independent account of identification. There certainly is a sense in which an agent who acts of his own free will identifies with the desires on which he acts, as he is himself the originating source of such desires. But this is not an independent sense of identification. It is a sense that we define in terms of the idea of desires originating in a free will. There is also at least the following independently characterizable sense of identification. Some people who take drugs against their will, and who struggle to overcome their addiction, ultimately give in, and so come to identify with their addiction in the sense of building all of their expectations around it. In other words, they come see themselves as hopeless drug addicts: this becomes their self-conception. But this is hardly a sense of identification that will help us understand the idea of those desires that originate in a free will.

There is something right about connecting freedom of the will with the possession of desires with which an agent identifies, however. Since agents are the originating source of such desires it does seem that, when they act of their own free will they express their true nature. The desires on which they act are, in some sense, essential to who they are. But though this seems right, it in fact suggests a quite different account of free will, one which does not depend crucially on our having an independent idea of what it is for an agent to have desires with which he identifies.

Since the Enlightenment we have come to conceive of people as being essentially truth-oriented reasoners. They are beings who have the capacity to recognize the truth and to respond appropriately to it. In so far as we are deliberators, what this suggests is that we are essentially beings who have the capacity to recognize and respond to the facts about what we have reason to do. Thus, according to this account, an agent whose will is free is someone who asks himself or herself what there is reason to do and, in answering this question, he or she is sensitive to the available evidence. This is not to say that he or she will inevitably acquire true beliefs about what there is reason to do, but it is to say that when he or she fails to do so, and when the evidence was available to him or her, one's failure will be traceable to a failure to exercise his or her belief-forming capacities appropriately: he could and should have formed the correct belief, but he failed to do so. Moreover, an agent whose will is free is someone who, in the formation of desires, is sensitive to the beliefs he has about what he has reason to do. Again, this is not to say that he will inevitably form desires that accord with his beliefs about his reasons, but it is to say that when he fails to do so, his failure will be traceable to a failure properly to exercise self-control: he could and should have formed the correct desire, but he failed to do so (Wolf, 1990).

As is perhaps clear, this conception of free will differ crucially from the one suggested earlier. What is important for freedom is indeed a capacity to desire otherwise, but the possession of this capacity is not to be analyzed in terms of what happens in nearby possible worlds in which the agent wants to want otherwise. Instead it is to be analyzed in the same way, whatever that way is, in which we analyze the ability rational thinkers possess to respond appropriately to evidence in the formation of their beliefs. Just as a rational thinker who fails to adjust his beliefs to the available evidence makes a mistake he should not have made, and so, we suppose, must have had the capacity to make the adjustment and believe rightly instead, so a rational deliberator who fails to form beliefs about what he has reason to do in accordance with the available evidence, or who fails to desire in accordance with his beliefs about what he has reason to do, makes a mistake he should not have made, and so is supposed to have had the capacity to control himself and acquire the correct belief or desire instead (Pettit and Smith, 1996).

Note two consequences of this account of freedom of the will. The first is that it looks tailor-made to provide an account of the conditions of moral responsibility. Those who have no capacity to believe that they have reason to do anything other

than they in fact believe they have reason to do, or to desire to do anything other than they in fact desire to do, can hardly be praised for having the right beliefs and desires, if it so happens that they are right, or blamed for having the wrong ones, if it so happens that they are wrong. This explains why we don't hold the alcoholic responsible. The irresistible nature of his desire to drink makes him incapable of an exercise of self-control, despite the fact that he believes, correctly, that he has reason to abstain. It also explains why we don't hold mice morally responsible for what they do. Their lack of cognitive sophistication deprives them of the capacity even to form beliefs about their reasons for doing what they do, let alone the capacity to desire accordingly.

Moreover, nothing other than the capacity to form the right beliefs and desires would seem to be required for people to be responsible either. This is why we hold the child described earlier morally responsible for failing to meet his parents at the appropriate time, notwithstanding the fact that he was locked in a prison cell and so could not have met them. We hold him responsible because we assume that his behavior was in fact the product of a desire he had which accorded with his beliefs about what he had reason to do, a belief that we take to be culpably mistaken. It is this that attracts our censure.

The second consequence concerns the possibility of freedom of the will in a deterministic world. A proof that freedom of the will is possible within a deterministic world would seem now to require no more and no less than a demonstration that individuals in a deterministic world have the wherewithal to possess just such a rational capacity. There have recently been attempts to provide such a demonstration (Smith, 2003; Vihvelin, 2013). But whether these particular attempts succeed or not, even on the face of it, there does not look to be any particular difficulty in principle involved in providing such a demonstration. We regularly discriminate between people who do and people who do not have rational capacities, and, in so doing, we seem to pay no regard whatsoever to issues of determinism. This is because, even if determinism is true, that only shows that people will make the mistakes that they make. It does not show that they could not help making those mistakes, in the sense of having no rational capacity to get things right.

But, whatever we ultimately come to think about the possibility of rational capacities in a deterministic world, the crucial lesson of this account of freedom of the will is that, if there do turn out to be such difficulties, then it is not just the idea of freedom of the will that becomes problematic, it is the very idea of a rational agent as someone who has the capacity to recognize and respond appropriately to the truth. Whether freedom of the will is possible in a deterministic world or not, its possibility goes hand in hand with the possibility of agents who have the capacity to form beliefs and desires in a rational manner.

Abstract

The French Revolution was a momentous historical event that set enduring patterns for modern revolutionary movements and for much of modern politics in general. Contemporary reactions to it fed into the development of many ideologies, from conservatism to communism. Scholarly controversies about the significance and interpretation of the French Revolution have been animated in particular by Karl Marx and Friedrich Engels' use of it as the prime example of a 'bourgeois revolution' that prepared the way for the triumph of capitalism. Although the controversies over the Marxist interpretation continue, recent scholarship has turned in new directions: gender relations; the notion of citizenship and its connection to religion, ethnicity, and race; and the intellectual history of the Revolution and its impact as an event in global history.

Introduction

The French Revolution was a momentous historical event that set enduring patterns for modern revolutionary movements and for much of modern politics in general. Contemporaries experienced the French Revolution as a set of interlocking changes or stages that seemed driven by some kind of mechanism or impetus. Analysis of this mechanism has preoccupied revolutionaries and scholars ever since. The conflicting political reactions to the French Revolution fed into the development of ideologies from conservatism to communism. Scholarly controversies about the significance and interpretation of the French Revolution have been animated in particular by Karl Marx and Friedrich Engels' use of it as the prime example of a 'bourgeois revolution' that prepared the way for the triumph of capitalism. Although the controversies over the Marxist interpretation continue, recent scholarship has turned in new directions: gender relations; the notion of citizenship and its connection to religion, ethnicity, and race; and the Revolution's impact on the colonies.

The year 1789 marks the clear beginning of the French Revolution, but opinion is much more divided about its ending: did it end in 1794 with the fall of Maximilien Robespierre, in 1799 with the rise of Napoleon Bonaparte, in 1804 when Napoleon established his empire, or in 1815 with the final defeat of Napoleon at the Battle of Waterloo? Debate on the question of endings cannot be resolved definitively because it is so closely entwined with interpretive questions. The choice of ending depends on the determination of the central significance of the French Revolution.

What most struck contemporaries and has fascinated commentators ever since was the unpredictability and yet seeming inexorability of the unfolding of events. Even in the middle of this unfolding, political actors and witnesses spoke of 'the system' of 'the French Revolution,' as if revolutionary events had an internal logic or mechanism pushing in a consistent direction. After spending years studying this logic, and having published his enduringly influential study of the French Revolution, Alexis de Tocqueville still complained of his difficulty in grasping 'this malady of the French Revolution,' this '*virus* of a new and unknown kind' (de Tocqueville, 1977).

Revolutionary Stages

As a series of political events, the French Revolution is usually divided into five periods or stages: the constitutional monarchy or liberal revolution of 1789–91; the second revolution and the Terror of 1792–94; the Directorial regime or liberal republic of 1795–99; Napoleon Bonaparte's consulate of 1799–1804; and the Napoleonic empire of 1804–15. This vertiginous succession of regimes established many of the prototypes of modern political authority and even much of modern political language, including the key distinction between Left and Right (determined by the location of deputies vis-à-vis the speaker in the National Assembly). The very possibility of ascertaining periods or stages – already apparent to contemporaries – raised questions about the natural history or morphology of revolution: Was it like a sickness or fever from which a polity eventually recovered? Or was it rather a kind of speeding up of historical development, a bootstrap up to the next stage of capitalism or modernity?

As the French Revolution moved from stage to stage, the revolutionaries generated at least three different models for modern (secular, nonmonarchical) political authority. By abolishing 'feudalism' (eliminating serfdom and seigneurial dues), suppressing noble titles, declaring the 'rights of man,' and founding the first French republic with universal manhood suffrage (1789–92), the French revolutionaries laid the foundations for democratic, representative government. By arresting dissidents, executing opponents, and carrying out a cultural revolution in the form of de-Christianization and republican political reeducation (the Terror of 1793–94), the revolutionaries set the mold for 'totalitarian' government with its repressive insistence on political conformity in the name of a future social good. Napoleon Bonaparte developed a third model of paternalist, authoritarian government by a state with a strong military caste. In other words, the French Revolution adumbrated virtually all the possibilities of modern political authority.

The Origins of Ideology

The French Revolution gave birth both to the term 'ideology' and to many different ideologies that have continued to

organize political discussion right up to the present day. Under the impact of revolutionary events, tradition lost its givenness, hierarchy no longer seemed natural, and monarchy no longer went without justification. The revolutionaries showed that society could be reorganized by an act of self-conscious political will (the definition of revolution itself). The attempt to reshape hearts and minds through festivals, paintings, engravings, operas, plays, and even ordinary items such as snuffboxes and playing cards drew dramatic attention to revolution as a mode of action. This attempt did not produce unanimity, however; rather it produced social conflict. As a consequence, revolution brought 'the social' as a category into sharper relief. As early as 1792, Antoine Barnave wrote his *Introduction à la Révolution française*, arguing that new forms of wealth produced ineluctably new forms of political authority (Barnave, 1988). As the social determinants of politics became more visible, i.e., more of a problem to be investigated, ideologies took shape as formal doctrines about the proper relationship between politics and society.

The first ideology to emerge from the French Revolution was conservatism. Its founding text, Edmund Burke's *Reflections on the Revolution in France* (1790), was written in response to the events of 1789. The National Assembly's efforts to remake the French constitution led Burke to denounce what he termed a new 'political metaphysics' based on natural rights and abstract reason. Unlike many reactionary royalists, however, Burke did not just excoriate the French Revolution as the incarnation of evil and impiousness. He understood that the revolutionaries were in the process of erecting an entirely new foundation for politics, and he undertook to counter them point-by-point. By arguing for a conservatism that accommodated change through practical experience and gradual amelioration, he admitted the necessity of confronting demands for change and the parallel demand for an elaborated doctrine to support the status quo. Even for conservatives, then, the French Revolution changed the rules of the game. The status quo now required explicit defense.

After 1789 liberal supporters of the Revolution also had to clarify their position. Most liberals supported the constitutional revolution of 1789 and rejected the Terror of 1793–94. This distinction was not always easy to uphold, for conservatives routinely accused liberals of supporting policies and positions that might open the way to more radical experiments, just as those of the revolutionaries of 1789 had opened the way to the Terror of 1793–94. The unfolding of stages in the revolutionary process thus shaped ideological debate, either explicitly or implicitly, for many generations after the French Revolution.

Socialists, and especially Marxists, traced their lineage directly back to the French Revolution. The early socialists – Claude Henri de Saint-Simon and Charles Fourier, for example – concluded from the French Revolution that society could be reorganized according to a technocratic project (thus 'utopian socialism' according to Marx). Marxists believed that only class struggle could produce a new social order. According to Marx and Engels, the French Revolution marked the overthrow of the aristocracy by the bourgeoisie. The bourgeoisie would develop capitalism on the ruins of the feudal order it dismantled, thus preparing the way for a subsequent revolution in which the proletariat formed by capitalist development would overturn the bourgeoisie and replace capitalism with communism. The French Revolution was therefore a crucial stage in the class struggle and an essential forerunner to the future communist order.

Marx's emphasis on the need for self-conscious revolutionary organization had been at least partially inspired by Gracchus Babeuf and his 'Conspiracy of Equals' of 1796. Although Babeuf had few followers and his plans were foiled by police infiltration, his dream of a revolutionary seizure of political power by a secretly organized conspiratorial group lived on through the efforts of the Italian revolutionary Filippo (or Philippe) Buonarroti. Buonarroti, a member of Babeuf's circle in 1796, published a history of the Conspiracy of Equals in 1828. It brought the message of revolutionary seizure of power to secret societies throughout Europe. One of Buonarroti's followers, the French revolutionary socialist Auguste Blanqui, combined Buonarroti's appeal for a secret revolutionary brotherhood with the idea of a 'dictatorship of the proletariat,' a term coined by Blanqui to define the political goal for socialism. Marx and Engels incorporated both Babeuf's and Blanqui's notions into their program for proletarian revolution.

The Foundations of Modern Social Science

Because the French Revolution brought the relationship between society and politics into sharper focus, it also accelerated the development of the social sciences, first in France and then more broadly in Europe. The Directory regime created the first research institute for the social sciences with its department of political and moral sciences in the Institut National des Sciences et des Arts. Bonaparte, himself a member of the Institute, took more than 150 scientific experts with him on his expedition to Egypt in 1798. They set up an Institut d'Egypte in Cairo and helped inaugurate 'oriental studies' in Europe. They also discovered the Rosetta Stone, which enabled experts to decipher Egyptian hieroglyphics.

The French Revolution had an especially dramatic impact on historical studies in France. The first full-length histories of the Revolution were published in the 1820s by François-Auguste Mignet and Adolphe Thiers, journalists and editors in the political opposition. They used the history of the French Revolution to defend the notion of a constitutional monarchy and to criticize the restored Bourbons. In the 1840s, Louis Blanc, Alphonse Lamartine, and Jules Michelet wrote histories of the Revolution as part of their campaign for a republic. Although Marx did not write a history of the French Revolution of 1789, he did read the French historians and made constant reference in his work to the French Revolution of 1789.

Marx was not alone in considering the French Revolution an important stage in historical development. As the notion of historical evolution spread in the nineteenth century, the French Revolution almost inevitably became an important benchmark. Auguste Comte, one of the founders of sociology, took as his point of departure the last writings of the Marquis de Condorcet, a French nobleman and revolutionary who committed suicide rather than face the guillotine in 1794. Comte proposed three stages of historical development: the theological, the metaphysical, and the positive or scientific. The French Revolution helped bring about the ongoing transition

to the third, positive stage by liberating modern social elements from the dead hand of the Old Regime. The task of social science was to complete this transition, which could only be accomplished finally in ideas and opinions, according to Comte, not by revolutionary action. The ultimate aim of his system was the reorganization of society by means of scientific sociology.

Alexis de Tocqueville, who helped lay the foundations for political sociology and political science with his *L'ancien régime et la Révolution* (1856), considered the French Revolution not as a stage so much as an accelerator of the general modern trend toward democracy and equality. Tocqueville had read the previous historians of the French Revolution, though he rarely cited them, and absorbed the view that social changes had inevitable political repercussions. He wove his analysis of social changes into a subtle examination of French political culture and especially the dominance of the central state. In so doing he created an alternative to the Marxist emphasis on class struggle. Tocqueville considered the French Revolution pivotal in the advance of modernity but largely negative in its effects. Tocqueville saw in the French Revolution the tendency of democratic revolution to reproduce the despotism of monarchical authority by leveling all institutions that might have provided a check on state power. Although the French made their Revolution for liberty and equality, they gave up liberty in order to be assured of equality and ended up with an equality of servitude to the Napoleonic state. This line of analysis had a long posterity – Hannah Arendt's analysis of revolution has clear affiliations to Tocqueville's – and continues to influence political and social theory right down to the present.

Scholarly Controversies Concerning the Revolution

Since analysis of the French Revolution has played such a prominent role in the development of competing political ideologies, it is hardly surprising that it has generated disputes among scholars as well. In the nineteenth century, writers used the French Revolution to argue for and against monarchy, empire, or republicanism as a form of government. After the eruption of the Russian Revolution in 1917, however, debate shifted to the terrain defined by Marxism and communism, and in particular, the French Revolution as the exemplar of bourgeois revolution.

Within France, Marxist historians of the French Revolution enjoyed the advantage of having captured the chair of the history of the French Revolution at the Sorbonne (University of Paris). For most of the twentieth century, the chair was occupied by a succession of talented socialists and communists. They pioneered the study of social tensions and social classes, of 'history from below.' The most remarkable of them was Georges Lefebvre, who wrote wide-ranging studies of the peasantry during the Revolution. Lefebvre's combination of narrative skills and analytical studies gave him an unrivaled reputation; even those who objected to his Marxist views regarded him as the most accomplished academic historian of the Revolution.

The Right did not have the same initial foothold within the French university system. Hippolyte Taine, for example, wrote his four volumes on the Old Regime and the French Revolution as a general literary and cultural critic, not as a professional historian. Taine's views remained fundamental to the Right wing criticism of the Revolution. He had nothing but contempt for 'the people' so beloved by Michelet. He frequently likened the lower classes to beasts or insects; at worst, they were a crazed, frenzied rabble. Augustin Cochin toned down this virulence, arguing that the lower classes were manipulated by professional politicians who came to power through the activities of secret societies such as Masonic lodges. The Right took up some of the claims of the Left – that the French Revolution foreshadowed the Russian Revolution of 1917 – but gave them a negative rather than a positive spin.

Before the 1970s, the Marxist Left enjoyed the dominant position in French academic debates, in part because of its strength within the university, and in part because the Right was associated with antidemocratic politics. The balance began to shift, however, as critics of the Revolution finally accepted the republican form of government. A more moderate republican Right got support from a growing body of work produced in the Anglophone countries, especially the United States and the United Kingdom, which attacked the central Marxist thesis that the French Revolution was a bourgeois revolution. Critics argued that the capitalist bourgeoisie had not made the Revolution (first aristocrats and then middle-class officials and lawyers had led it, not manufacturers); that the Revolution had not overthrown feudalism (because feudalism no longer existed); and that the Revolution did not pave the way for capitalism (since industrialization did not take place until the 1840s).

François Furet, a former communist, brought together the new Anglophone work in a frontal assault on the Marxist interpretation. This 'revolutionary catechism,' 'Lenino-populist vulgate,' he argued, fundamentally distorted the history of the French Revolution by depicting it as a class struggle that anticipated communism. Furet claimed as his ancestors Tocqueville and Cochin; he did not reject democracy, but rather wanted to understand why democracy in the French Revolution developed into Terror or totalitarianism. The social underpinnings of the French Revolution could never explain this skidding out of control into Terror, he maintained; revolution was an autonomous political and ideological movement, not the expression of a social class (Furet, 1978). By 1989, the year of the bicentennial of the French Revolution, Furet's version of the French Revolution had become the new orthodoxy. The political balance had shifted, not only in France but almost everywhere else as well. The French Revolution no longer seemed a communist preserve.

Since 1989, as the polemics over Marxism have subsided, the work of historians from other countries has attracted more attention. American, British, German, and Italian historians now offer alternative views of their own. No one school, whether Left wing or Right wing, French or Anglophone, currently dominates the historiography of the French Revolution. The shift of political interest away from Marxism has opened up new areas of research, including gender relations, definitions of citizenship, and the role of the colonies. These new perspectives reflect concerns with human rights and globalization, and with the relationship between politics and political economy, and between the Revolutions and international relations, themes emphasized by scholars emphasizing the importance of the intellectual history of the 1790s.

Since the French Revolution began by enshrining the notion of 'the rights of man,' it has been a prime site for work on the dilemmas of universalism. Feminists have pinpointed the Enlightenment's masculinist bias as the chief cause of the failure of the revolutionaries to include women in their promise of citizenship; so-called Enlightenment writers, such as Montesquieu and Rousseau, used nature and reason to justify women's exclusion from the public sphere, and the revolutionaries simply drew the logical conclusion from these assumptions. Other feminists, however, have insisted that the Revolution opened up new opportunities for women, legalizing divorce, assuring equal inheritance to girls, and affording women the opportunity to establish political clubs. Unlike women, men who were Protestants, Jews, free blacks, mulattos, or even slaves gained political rights during the French Revolution. Yet even these enfranchisements revealed telling fault lines in the revolutionary conception of citizenship; the National Assembly, for instance, insisted that the Jews must give up their particular identity and corporate privileges as Jews in order to become French citizens. Since discussions of free black and slave rights inevitably involved the slave colonies, and since France's colony of Saint-Domingue (San Domingo) was home to the first successful slave revolt in history beginning in 1791, the interest in citizenship has also stimulated study of France's slave colonies. Because the French Revolution made revolution an acceptable element of politics, and because so many have seen the Revolution as the origin of the modern world, it remains of singular significance.

Abstract

Sigmund Freud (1856–1939) the founder of psychoanalysis, was born in Freiberg, Moravia. He qualified in medicine at the University of Vienna and published almost 200 neuroscientific papers. But a visit to Charcot in Paris aroused his interest in hysteria and hence psychological development, both normative and abnormal. His first major psychoanalytic work, *The Interpretation of Dreams* (1900), was partly founded on his self-analysis, using the technique of free association. Intensive clinical investigation led to his elaboration of the concept of a mental organization inaccessible to introspection, and to formulations of preconscious mental functioning frequently, though not invariably, accessible to consciousness. Freud was always prepared to modify his views in the light of further experience: the most radical changes were described in the *Ego and the Id* (1923) and included, *inter alia*, the concept of unconscious guilt. He wrote extensively on the application of psychoanalysis to nonclinical fields, including sociology, anthropology, group psychology, and religion. When the Nazis occupied Vienna in 1938, he left for London with members of his family, warmly welcomed by the British Psychoanalytical Society. Within 15 months he died from a longstanding and painful cancer of the jaw. He wrote until the end.

Family Background and Early Life

Sigmund Freud, neuroscientist turned founder of psychoanalysis, was born on May 6, 1856, in Freiberg, Moravia, now part of the Czech Republic. His father, Jakob (1815–96), a wool merchant, came from Galicia, and married Amalie (1835–1930, neé Nathansohn), 20 years younger, when he was 40. Jakob had two sons by a previous marriage, Emanuel and Philipp. Jakob was warm and affectionate, with a strong sense of humor, and Freud evidently admired and respected him. Amalie was a lively and attractive woman who was proud of Sigmund, her first-born.

The family multiplied quickly: five daughters and two more sons were born within 10 years. The first of these, Julius, died when 8 months old and Sigmund was aged 19 months. Both parents were Jews, with no religious affiliations, though a devout Catholic Nanny took Sigmund to Church. She left when he was two and a half. A nephew, John, a year older than Freud was very close to him: the two fought and played together. That childhood ambivalence, Freud reflected years later, must have had a profound effect on his character and on his ability to defend himself (Freud, 1900).

Financially, times were hard. In 1859 the family moved to Leipzig, and in the following year to Vienna. Freud missed the beauty of the countryside round Freiberg. Although the children were well looked after, poverty was not assuaged by rapid family growth. By 1875 family fortunes improved: Amelie's family were helping, making possible a move to a larger house. Freud had a room of his own that served as a study.

Freud's memories of his childhood as revealed in his writings are without early detail, but one unforgettable recollection was of urinating in his parents' bedroom while they were present. Reprimanding him, his father said bluntly: 'The boy will come to nothing!' Freud's wounded ambitions were reflected recurrently in dreams in which he listed his achievements as if to say: 'You see! I have come to something!' (Freud, 1900; see also Shengold, 1993).

Education and Early Interests

Freud's schooling began with his mother, until his father took over before sending him to a private school. Freud learned rapidly, and was reading Shakespeare (whom he loved all his life) from the age of eight years. When nine years of age, he won a place at the Sperl Gymnasium, where he was a distinguished pupil, passing out, at 17, with the distinction *'summa cum laude.'* He became an accomplished linguist, with a firm foundation in Latin and Greek, a sound knowledge of Hebrew, fluency in English and French, and good Italian. He corresponded with an adolescent friend in Spanish. He became one of the greatest stylists in the German language (Kaufmann, 1980). He studied at every opportunity. He loved the Arts, but took an early dislike to music, which he never felt able to appreciate. He was fond of walking, swimming, and skating. He liked travel, and made his first visit to England at the age of 19.

Early Career and Scientific Outlook

Freud (1925) said that curiosity and human concerns motivated his interest in medicine, but it was 'hearing Goethe's beautiful essay on Nature read aloud ... that decided me to become a medical student.' He was attracted strongly by Darwin – a necessary step towards his own evolutionary approach to the history of the individual's mental development. His neurological work was affected profoundly by the evolutionary approach of John Hughlings Jackson, the founder of modern neurology. Furthermore, Freud's admiration of Goethe as scientist as well as writer was life long. Goethe's belief in the importance of observation and reflection was profound, and his meticulous examination of a single sheep's skull in 1790 led to his deduction that the vertebrate's skull developed from vertebrae. This type of detailed study – applied by Freud to the individual case – is the essence of poetic (or romantic) science that stands in contrast with (though not

in opposition to) Newtonian (or classical) science. (Goethe's unfortunate opposition to Newton's theory of color does not vitiate this point.) In psychology, the corresponding distinction is between the ideographic (romantic) approach and the nomothetic (classical). Both methods have drawbacks and advantages; for Freud's psychology, in particular, the nomothetic approach has serious limitations. The distinctions have been discussed extensively by Kaufmann (1980) and by the founder of modern neuropsychology, Luria (1979). It is impossible fully to appreciate Freud's work outside this context.

Freud began his medical training in October 1873 and qualified MD in March 1881. The years were crowded: Freud dealt with the tedium of a year's compulsory military service by translating a book by John Stewart Mill (Jones, 1953). He was influenced by many illustrious figures, none more important than Ernst Brücke (1819–92) head of the Institute of Physiology. Freud, as a research scholar, studied the histology of nerve cells, and his work led to a number of significant conclusions. After qualification, Freud continued working at the Institute, where his love for research had full scope. He had already found 'rest and full satisfaction' there (Freud, 1925).

Neuroscience

But in 1882 Freud was still poor and, reluctantly, accepted Brücke's advice to practice medicine. He left the laboratory to start work in the General Hospital. He spent 6 months under Theodor Meynert (1833–92), the Professor of Psychiatry, whose work and personality Freud greatly admired. His research at the Institute of Cerebral Anatomy led to important publications. He began to study nervous diseases, and quickly established a reputation as an outstanding diagnostician. He was still urgently short of money: he was by now engaged to Martha Bernays (1861–1951), and the need to earn enough to keep a wife and family was compelling.

In the spring of 1885 Freud was appointed Lecturer (*Dozent*) in Neuropathology. Brcke's influence resulted in the award of a valuable Traveling Bursary, and Freud fulfilled an old ambition to visit Paris and learn from Charcot at the Salpêtrière. His offer to translate a new volume of Charcot's lectures into German was accepted by the great man, and Freud was soon admitted to Charcot's inner circle. Charcot's lectures and demonstrations were outstanding, but Freud was astonished by his investigations into hysteria. Charcot demonstrated that hysterical symptoms were genuine; that hysteria was common in men as well as women; and that hysterical paralyses produced by hypnosis were identical with spontaneous attacks. Charcot met skepticism with patience and firmness: once, faced with an objection made on theoretical grounds, he replied: 'Theory is all very well, but it doesn't stop facts from existing.' Freud never forgot that remark.

The Paris visit changed the direction of Freud's career. Charcot had broadened his grasp of neurology, but the neuroses had captured his imagination. He left Paris at the end of February 1886, intent on further investigations of hysteria. But before he returned to Vienna he stayed for some weeks in Berlin to study nervous disorders in children, and this important detour led in time to the publication of a number of monographs. Freud's report on his visits, to his sponsors in Vienna, is a model of clarity and concise exposition (Freud, 1956).

Indeed, Freud's interest in neuropathology by no means stopped abruptly. Important papers lay ahead: observations on hemianopsia in two very young children (Freud, 1888) and his monograph on *Aphasia* (Freud, 1891b) occupy a permanent place in the history of aphasiology. Freud had already abandoned the strict localisation theory of brain functioning – to which Meynert strongly adhered – in favor of the hierarchical model, with its concomitant theory of evolution and dissolution of the nervous system, advanced by Hughlings Jackson (e.g., 1884). Freud recognized the importance of these major advances, which were otherwise scarcely appreciated for another quarter of a century. With his young friend Oscar Rie he wrote a work on the unilateral cerebral palsies of children – a book still of repute in neuroscience (Freud, 1891a). Freud's overall contributions to the field were massive, and he published around 200 papers.

On his return to Vienna, however, Freud was trying to build up a practice to support a family: he married Martha in September 1886, starting a life long partnership of unusual harmony and mutual support. Both were devoted to their six children: in order, Mathilde, Martin, Oliver, Ernst, Sophie, and Anna – the only one to follow Freud into psychoanalysis. The first 5 years of marriage covered the closing phase of neurological work, and saw the growth of a friendship with the distinguished physician Joseph Breuer (1842–1925), with profound effects on Freud's career.

The Birth of Psychoanalysis

Between 1880 and 1882 Breuer had treated the now famous Frau Anna O. for severe hysterical symptoms, including multiple limb paralyses, disturbances of sight and speech, contractures, an intense cough, and anorexia. Accounts of the illness, its treatment, outcome, and significance for the foundations of psychoanalysis, and its effect on the Breuer–Freud friendship vary (e.g., Breuer, 1882; Breuer and Freud, 1895; Freud, 1914, 1925, 1932; Jones, 1953; Gay, 1988; Ellenberger, 1972; Hirschmüller, 1989), but, at the risk of distortion by brevity, the present summary seems safe. Anna O. suffered from states of autohypnosis alternating with near-normality. When, under self-hypnosis, she recounted the history of one of her symptoms, recalling the details of its first appearance, Breuer was astonished to find that it disappeared. Under induced hypnosis other symptoms were treated in similar fashion, and the method was christened the 'talking cure.' Breuer told Freud about it in 1982, and during the next two years they discussed it repeatedly. But, in Paris, Charcot showed little interest in the story, and Freud allowed the matter to lapse.

Back in Vienna, Freud treated a number of hysterical patients by hypnotic suggestion. But 'recovery' was too often transient, and Freud's interest in Breuer's treatment of Anna O. revived. When her first symptom appeared, the patient was nursing her dying father, and her recall resulted in 'abreaction' (the release of pent-up emotion attached to the event).

Adopting this 'cathartic method' over several years, Freud repeatedly confirmed Breuer's findings. The links with traumata were hitherto unconscious.

A preliminary communication by Breuer and Freud (1893) preceded the *Studies on Hysteria* (Freud, 1895d). Breuer contributed a theoretical chapter and an account of Anna O; Freud, four case histories. Differences of opinion became a strain in 1894, and the collaboration ceased in 1896. Freud valued Breuer's achievement, but was thinking on different lines. Breuer believed that pathological processes arose during 'hypnoid states' (e.g., Anna O's autohypnosis). For Freud, this begged the question of how 'hypnoid states' arose. He considered that psychoneurosis involved psychic defences against unacceptable internal states of 'emotional excitation,' habitually sexual in kind. The actual neuroses, however, were states of anxiety arising from unrelieved sexual excitation linked with abstinence or *coitus interruptus*. Breuer could not accept these views; he had failed to find any sexual component in Anna O's disturbance. But Breuer had never recognized Anna O's strong attachment to him ('transference') as sexual; alarmed by its intensity, he brought the treatment to an end. Anna O. responded to this loss with a phantom pregnancy (Freud, 1932). Breuer continued to see mentally ill patients, but never again used the cathartic method.

In time, Freud abandoned the use of hypnosis altogether. The power of transference (from the patient's unrecognized re-experience, in the treatment process, of infantile relationships) meant that excellent clinical progress could still be vitiated by disturbances in the doctor/patient relationship. That recognition profoundly affected the future development of psychoanalysis.

For a time, Freud used encouragement, persuasion, and similar measures as aids to treatment, but increasingly found them unnecessary. They were replaced slowly by the developing technique of free association, which took over completely by 1897–98. The patient lay on a couch (as before) with the analyst sitting behind him, but was now expected to try to say everything that entered his mind, irrespective of apparent irrelevance, distastefulness, or indiscretion. The analyst listened impartially, without giving more weight to any one utterance than he did to another. This major shift in clinical method had surprising results. Conflicting mental forces, undetected by hypnosis and related devices, were now revealed. Memories of striking internal and external mental experiences in early life had been denied access to consciousness because they had been 'alarming or painful or shameful by the standards of the subject's personality' (Freud, 1925). Memory was actively opposed by the force of repression, experienced by the clinician as resistance to unwelcome material. Forces striving to break through this barrier stemmed from the drives, founded substantially in infantile sexuality.

Psychoanalytic Career

Until the spring of 1897 (Jones, 1953) Freud believed his female adult patients whose associations pointed to seduction in childhood, usually by the father, as the traumatic root of their illness. But what at first presented as memory was found increasingly to be fantasy. Seduction in childhood undoubtedly occurred, but could no longer be invoked as the root of all neurosis. As it stood, Freud's theory was wrong. This devastating conclusion nonetheless pointed to the importance of fantasies in mental life, and to the realization that fantasy that is dynamically unconscious, that is, inaccessible to introspection, had all the force of reality since it could not be tested in the light of objective experience. A second, fateful, event, did more to foster psychoanalytic thinking than anything else: Freud courageously (and painfully) undertook his self-analysis, beginning in 1897 and continuing systematically through and beyond the writing of *The Interpretation of Dreams* (1900). With interruptions, it was life long.

Freud's letters to his friend Wilhelm Fliess (1858–1928), an ear, nose, and throat specialist living in Berlin, provide a unique source of information about these events. Never intended for publication, they were rescued by Princess Marie Bonaparte of Greece (the letters from Fliess have not survived). Starting in 1887, they set out in astonishing detail Freud's reflections, doubts, and formulations as they arose, and can be followed until after the turn of the nineteenth century. An edited version (Freud, 1954) was followed by the complete letters (Masson, 1985). The demise of the seduction theory and Freud's comments on his self-analysis are described in both.

The self-analysis was crucial for the development of basic psychoanalytic concepts. The richness and complexity of infantile life, including its sexuality, was not fully appreciated until well after *The Interpretation of Dreams* saw the light of day. The Oedipus complex, for example, is described in that book, but its fuller significance was underlined only in footnotes added much later. But Freud regarded the dream book as his single most important work. With copious illustrations from his self-analysis and clinical experience with patients, the study goes beyond the meaning of dreams and approaches the baffling problem of how the mind works.

The theory is involved, but a few key points may be mentioned. The function of dreaming is the preservation of sleep. Stimuli arising from outside the organism (noises, the pressure of bedclothes) or from within (pain, excitation), could often be contained when switched into nonmotor channels (dreaming). The formation of the dream is more complex. In normal waking life, accessible mental content is either conscious at any given moment, or is preconscious – capable of reaching awareness with varying degrees of difficulty. But some mental content is dynamically unconscious – barred from reaching the preconscious by repression. During sleep, this barrier is relaxed, and a partial regression to earlier forms of thinking allows normally unacceptable childhood wishes to find expression, though only in disguise. Even in sleep a censorship is partially operative, and the result is a distorted representation of infantile wishes that gives the dream its seemingly bizarre character. Any semblance of coherence is imposed during waking and recollection: the repression barrier is restored and the dream is (unwittingly) clothed in a measure of rationality.

The recollected (manifest) dream content arises from several sources. Stimuli that threaten sleep are the most obvious, but events and experiences of the day before

(day residues) are also used as building blocks. These have no intrinsic importance: they simply provide convenient representations for forbidden wishes. But emerging wishes are themselves distorted by primitive thinking before they are disguised further by the censorship. For Freud, the dream was a hallucinatory wish fulfillment, though generally far removed from the wishes of everyday appearance.

Do dreams provoking anxiety or portraying punishment also conceal wishes? Freud argued that, even in sleep, a wish can be so strong that its forbidden character can still be recognized and occasion distressing anxiety. In punishment dreams, the transgression portrayed brings with it a wish for punishment. This became clearer still when Freud, later, had conceptualized an unconscious sense of guilt.

The model of the mind outlined in the dream book was the foundation for all Freud's later theoretical formulations. Since it was written during his self-analysis, his pride in it also reflected a new self-confidence. Jones (1955) claims that, at the age of 45, Freud had reached full maturity: intellectual development, always precocious, had not hitherto been matched emotionally. For many years there had been 'continual periods of restlessness, uncertainty, instability and even more definitely neurotic disturbance.' A deep self-assurance had been hidden behind 'strange feelings of inferiority, even in the intellectual sphere.' He had over-idealized men who were, certainly, important to him; of these, Breuer had already withdrawn his support, and the relationship with Fliess was loosening. Self-analysis had revealed the neurotic nature of the tie.

Intellectual loneliness did not diminish productivity. *The Psychopathology of Everyday Life* (Freud, 1901) dealt with unconscious motivations in forgetting, slips of the tongue and pen, as well as some 'accidents.' The *Fragment* of Freud's analysis of 'Dora' (1905) described her treatment in 1900. *Three Essays on the Theory of Sexuality* (Freud, 1905) met with ferocity hard to imagine today. Freud had widened the concept of sexuality: all existing definitions failed to fit the facts and could not, for example, account for the sexual perversions. Sexuality was now understood within a much wider, developmental perspective. It was considered diphasic: development from infancy to roughly the age of five, centered around bodily erotogenic zones, was followed by a period of comparative quiescence (latency) before a second stage of sexual efflorescence started around puberty. *Jokes and their Relation to the Unconscious* (Freud, 1905) arose out of the work on the dream book.

The Growth of the Discipline

By the time these works appeared Freud was no longer intellectually isolated. Already, in 1902, two young Viennese doctors, Kahane and Reitler, and, more famously, Stekel and Adler were intrigued by psychoanalysis. Freud invited them to meet him for discussions; they gathered together on Wednesdays as 'The Psychological Wednesday Society.' This was the nucleus of an expanding group renamed, in 1908, the Vienna Psychoanalytical Society. By then much had happened. In 1904 Eugene Bleuler, Professor of Psychiatry in Zurich, wrote to inform Freud that he and his staff, most notably his Chief Assistant, C. G. Jung, had been making use of psychoanalytic ideas for the past two years. (In particular, Jung had applied them in his word-association tests.) By 1906 Freud and Jung were corresponding, and in 1907 Jung visited Freud in Vienna. The friendship grew rapidly and when, in 1910, the International Psychoanalytic Association was formed, Freud asked Jung to be President. Jung's bearing, intellect, qualities of leadership, psychiatric background, and dedication seemed suitable qualifications. Freud was attracted by his personality and regarded him as his 'son and heir.' Jung was greatly impressed by Freud's penetrating intellect. The rise and fall of their relationship is chronicled in their correspondence (McGuire, 1974).

Otto Rank had joined the group in 1906; and Karl Abraham, a major figure in the psychoanalytic movement, had long been fascinated by Freud's work when he visited him in 1907. Again, the correspondence between the two gives a vivid picture of their relationship; it continues until Abraham's premature death in 1925 (Abraham and Freud, E. 1965). In 1907, too, Sandor Ferenczi visited from Budapest, establishing himself the following year as a major figure in the discipline. With the visit of Ernest Jones in 1908, and Hans Sachs in 1910, Freud had a close circle of friends and collaborators.

In 1908, Jung organized an international conference in Salzburg. Freud's work was now discussed widely, in Europe, the USA, and Australia. In 1909 Freud lectured at Clark University, Massachusetts, accompanied by Ferenczi, Jones, and Jung. In 1910 a second international congress was held at Nuremberg, organized by Jung. But internal dissent soon surfaced. In 1911 Adler defected: to Freud's dismay, he refused to try to resolve their conceptual differences. Stekel, gifted, charming, but scientifically unreliable (Jones, 1955) left about the same time. Although Freud disliked leadership, he was a fatherly figure for his young colleagues, and bickering and rivalry, especially among the Viennese (cf. Jones, 1955) threatened stability. Freud's obvious preference for Jung was resented. But by 1912 Jung was showing signs of disaffection. Many Swiss psychiatrists denounced Freud's theory of sexuality, and, during a course of lectures in the United States Jung omitted any reference to it. Personal relations between the two men cooled, but it was not until 1914 that Jung left the movement on the grounds of incompatible views. The story of the rupture is complex: the Freud/Jung letters and the account by Jones (1955) repay study.

Freud's continuing productivity defied these dissensions. He addressed the problem of the sexual enlightenment of children (Freud, 1907), discussed children's sexual theories (Freud, 1908), and considered the relationship of the character traits of orderliness, parsimony, and obstinacy to anal eroticism – a paper greeted with indignation when it appeared (Freud, 1908). He tried to show that psychoanalysis could contribute to the understanding of art in discussions of Jensen's *Gradiva* (Freud, 1907) and of the relationship between creative writing and day dreaming (Freud, 1908). He wrote many other papers in these industrious days.

Two extensive clinical studies appeared in 1909. The first (Freud, 1909) describes the very first analysis of a child, though one undertaken by proxy. The successful treatment of 'Little Hans,' who had developed a phobia of horses, was carried out by his father, under Freud's supervision. Hitherto, the

childhood roots of neurosis in adults had been understood through a process of reconstruction; with Little Hans those sources could be identified at the time they were operative. Freud believed that the analysis could not be conducted by a stranger, and that the affection and authority of the father (in this case, a physician, too) made treatment possible. Child analysis as a speciality was yet unborn. It was many years before the possibility of directly analysing young children, under favorable conditions, was recognized.

The second patient suffered from an obsessional neurosis (Freud, 1909). The symptoms included fears that harm would befall his father and a woman he admired; compelling impulses, one of which was to cut his throat with a razor; and self-imposed irrational prohibitions. He was horrified but attracted by an account of a punishment in which rats ate their way up the victim's rectum. The unconscious sadism underlying his 'fascination' with the torture was among the features on which the analysis cast light. A deeper psychoanalytic formulation of obsessional neurosis emerged from the treatment. Later critics of this case report, and that of Dora, have suggested that Freud neglected the role of the mother in the genesis of the disorders. But Dora's treatment was brief, unfinished, and took place when clinical analysis was still in its infancy. In the case of the Rat Man, the criticism, when sound, is largely based on hindsight.

Another case study (Freud, 1911) concerned a subject whom Freud had never seen. Dr Schreber suffered from a paranoid state, and was under care for 6 years. He later wrote his *Memoirs of My Nervous Illness*, though Freud read them only in 1910. The illness fell into two phases: distressing delusions of persecution preceded delusions of grandiosity. Freud made an ingenious and fascinating reconstruction of the course of the illness. His work stimulated much clinical research. Psychoanalytic theories of psychotic illness fall into two broad groups: either it is part of a neurosis–psychosis continuum, or, unlike neurosis, it involves the loss of higher psychic functions and the re-emergence of more primitive ones, hitherto kept in check by the lost capacities. Many claim that Freud supported the first (unitary) theory; others the second (discontinuity theory). The controversy deserves close attention and is summarized elsewhere (Yorke et al., 1989).

In 1910 Freud (1910) published a study of a childhood memory of Leonardo da Vinci, and the first of three essays on the psychology of love. In 1911, the first of a series on psychoanalytic technique, and from 1910 to 1912 some short papers on theory that paved the way for later and larger works. An excursion into social anthropology, *Totem and Taboo*, was written between 1912 and 1913. Before war broke out in the summer of 1914, Freud's works included a history of the psychoanalytic movement (Freud, 1914), giving his version of the disagreements with Adler and Jung; a fascinating paper on the *Moses* of Michelangelo (Freud, 1914); a discussion of the scientific status of psychoanalysis (Freud, 1913); and a wide ranging paper on narcissism from which so many ideas were later developed (Freud, 1914). These were productive years indeed.

During the war Freud was anxious about two of his sons involved in it. Martin fought in Galicia and Russia; Ernst against Italy after that country entered the conflict. Martin was decorated for gallantry. Medical reasons prevented Oliver's acceptance by the army. Optimism about the outcome diminished after 1915. In 1916 the food shortage began to bite and got worse as the war continued. Freud had few analytic patients. Contact between analysts faced obstacles, some severe, even in the central powers.

For all the difficulties, Freud continued to write. He wrote 12 papers on the theoretical basis of psychoanalysis between 1914 and 1917: only five were published, and a sixth manuscript was found in 1983. There is no trace of the others. *Thoughts for the Times on War and Death* (Freud, 1915) anticipated the correspondence with Einstein (Freud, 1933) *Why War*? At the University, in the winter terms of 1915–16, and 1916–17, Freud gave a total of 28 lectures on psychoanalysis, and wrote them down, from memory, later (Freud 1916–17). Important changes were made in the *New Introductory Lectures* (Freud, 1933), but, taken together, the two series offer an excellent entry into Freud's psychological thinking. The most extensive of Freud's case histories (the *Wolf Man)*, written in 1914, was published much later (Freud, 1918). In 1919 the baffling problem of masochism (sexual pleasure in pain), and a psychoanalytic look at 'the uncanny' (Freud, 1919) were among the many subjects Freud addressed.

The return of many old colleagues to Vienna in 1919 ended wartime isolation. For some time life was hard, but psychoanalysis continued to grow worldwide. In 1919 Martha Freud contracted influenza leading to pneumonia and was ill for many months; the following year Sophie Freud died from a similar cause. Freud grieved deeply.

In 1923 Freud's heavy cigar smoking seemed responsible for a growth affecting the jaw and palate, removed surgically. This was the first of many operations for cancer that Freud survived over the next 16 years, bearing discomfort and pain, often severe, with fortitude. But he continued to work. In that same year, he set out major changes in psychoanalytic theory (Freud, 1923). He had already felt obliged to give aggression (more accurately, destructiveness) the same status as libido. For clinical and theoretical reasons the structure of the mental apparatus was redefined. The ego was now the executive mental agency, holding a balance between the conflicting demands of reality, the id, and the superego. The id strove for immediate drive gratification; its mentation followed the primitive primary process; and its content was dynamically unconscious. But it intruded into an unconscious part of the ego where it encountered checks and controls against inappropriate discharge. The superego was thought of as a greatly extended conscience, based on internalized but modified parental aims and proscriptions, but a substantial part of its operations were unconscious. Its functions included that of the earlier censor. With the aggressive drives of the id partly at its disposal, it put pressure on the ego to withstand those inner urges that ran counter to its prohibitions, aims, and ideals. It was responsible for the sense of guilt, conscious, and unconscious. It must be added that higher mental functions such as conscious thinking and reflection (secondary process), reality testing, and judgment were functions of the ego.

Freud continued to elaborate and modify this model (it should not be reified). He made radical changes in his theory of anxiety (Freud, 1926); extended his work on masochism (Freud, 1924); and in the field of social psychology added to his earlier study of the psychology of groups (Freud,

1921) the far reaching *Civilization and its Discontents* (Freud, 1930). The work of his female colleagues and his own clinical experience led him to re-examine the many problems of female sexuality (Freud, 1931, 1933). This work aroused opposition, particularly among feminists: Eissler (1977) countered some of these criticisms, but there have been many subsequent developments. It is worth remembering that Freud's close friendships included many women (see, e.g., Freud and Andreas-Salome, 1972); and many found his work did much to reduce guilt about sexuality. In *Analysis Terminable and Interminable* Freud (1937) emphasized the therapeutic limitations of psychoanalysis, but he was apprehensive about the possible reception of *Moses and Monotheism* (Freud, 1939), which extended his inquiries into early social organization *(Totem and Taboo* 1912–13, *Group Psychology* 1921).

Exile: England

In 1938 the Nazis entered Vienna. Freud's books had already been burned in Germany (Freud thought this more advanced than burning him). Through the good offices of Princess Marie and Ernest Jones Freud, together with Martha, their daughter Anna, and others, were allowed to leave for London. Freud was quite ill and tired by the journey, but was pleased by the warm reception that awaited him. The British Psychoanalytical Society gave him a house at 21 Maresfield Gardens in Hampstead. Anna Freud was his devoted nurse. His remarkable *Outline of Psycho-Analysis* (Freud, 1940) was written there. It was there, too, that that death ended his considerable pain and suffering on September 23, 1939. His ashes remain at Golder's Green Crematorium.

Of his many honors, he particularly valued the award of the Goethe Prize for Literature (1930) and his Corresponding Membership of the Royal Society (1936).

Freud's Impact on Twentieth-Century Thought and Culture

There is still a widespread view that Freud's impact on twentieth-century thought, on the arts, sciences, social attitudes, and beliefs, has been far-reaching, even immense. Almost every intellectual discipline, it is said, has been influenced by his ideas. The importance of unconscious motivation is acknowledged widely. Furthermore, many of his concepts – such as the 'Freudian slip' of pen or tongue – have passed into the common language of everyday social intercourse; and his views on sexuality have had a liberating impact on social attitudes and broadened sexual mores.

This view is by no means universal. Freud is undeniably a household name, but more than any other major figure, is the subject of widely varying and conflicting claims. These differences may arise in part from the nature of his subject, for it may be said, with a certain truth, that every man is his own psychologist. They may also arise from an investigative method difficult to understand without personal acquaintance. Freud's neuroscience aside, his principle field of inquiry was subjective and internal, and not readily open to methods appropriate to objective and external research. Many academic psychiatrists and psychologists consider that both Freud's clinical method and his theoretical constructs lack empirical support: in this, they generally equate empiricism with mensuration.

This fact stands in the way of dispassionate assessment even for those actively and intelligently involved in debate. The casual bystander, faced with controversy on a substantial scale, may be simply bemused or follow an opinion in line with personal appeal. And if the intelligent and industrious layman turns to Freud's own writings, he will still encounter significant obstacles. Freud's ideas cannot be picked up piecemeal, but comprehensive reading is difficult without informed guidance. Moreover, reliable introductory works are hard to come by. So it seems unlikely that the forces behind the 'Freudian slip,' and the distinctions between the preconscious and the unconscious, are understood widely. (The term 'subconscious' is more likely to be heard – a word Freud never used except by way of criticism.) Finally, while the liberalization of sexual attitudes may owe something to Freud, social, economic, and political forces are surely of greater importance. These include the availability of reliable contraception.

Indeed, Freud's views on sexuality, when they are not bowdlerized, are misunderstood widely. But the wider point to be made is this. Most people, in all sections of society, who have any interest in Freud, do not know what he really said. They only know what they think he said. And that is just as true for most critics and commentators who seemingly write with authority, including psychologists, 'hard' scientists, sociologists and art critics, whether the views they express are positive or negative. The viewpoint expressed here may at first seem novel. It was presented in extended form at a meeting of the *Psychoanalytic Heritage Foundation* on October 6, 1992, when it became evident that many Freud scholars were thinking on similar lines. At the recent Conference in London (see below), Douglas Watts stated from the platform that psychoanalysts needed to do more to make the general public more familiar with Freud. 'At present all they have is a caricature.'

For reasons that are not dissimilar, though highly complex, even psychoanalysts have widely diverse approaches to both theory and clinical practice and to the weight they attach to basic Freudian principles (Yorke, 1995). Psychoanalysis is avowedly pluralistic (Wallerstein, 1988, 1990). And although psychotherapy is often said to derive from the 'talking cure,' similar considerations apply.

In a few instances, Freud's influence, directly or indirectly, on other disciplines is evident, though localized. Disciplines not already mentioned include: education (e.g., many members of the Montessori movement); criminology (The Institute for the Study and Treatment of Delinquency in London); family law in relation to children (e.g., liaison between the Child Study Center and the Law School at Yale University). Properly understood, Freud's work and its true derivatives is capable of fostering advances in many intellectual and sociological fields.

It is pleasing to end on a positive note – in relation to Freud's first love, neuroscience. Freud always hoped that the underlying basis for mental activity in terms of the functioning brain would, one day, yield to investigation. For the greater part

of a century that hope seemed slim indeed. But the last few years have brought startling developments. Solms (1997), for example, in a fascinating series of experiments, showed convincingly that the neuropsychology of dreaming was very much in line with the argument set out in *The Interpretation of Dreams*. Work on the neuropsychology of affects, for example, attracted interest from an increasing number of psychoanalysts, and in 1999 a new scholarly journal, *Neuro-psychoanalysis,* was founded. In the first issue, Solms and Nersessian (1999) demonstrated, in a wide-ranging survey, the extensive nature of Freud's contributions to affect theory. On July 21–23, 2000, the first annual Neuro-psychoanalysis Conference was held in London entitled *Neuropsychology and Psychoanalytic Persepectives on Emotions,* addressed by the world authorities Jaak Panksepp, Antonio Damasio, and Mark Solms, and introduced by Oliver Sacks. The meeting was a heartening success, and the compatibility between the findings of the two disciplines was seen to be remarkable.

Abstract

Gilberto Freyre (1900–87) was not a professional academic, although he held appointments as a visiting professor of sociology and anthropology. However, he made contributions to both disciplines, as well as drawing upon economics, geography, and psychology in his classic studies of the social and cultural history of Brazil, notably the trilogy he published on the subject between 1933 and 1959.

Gilberto Freyre (1900–87) was born in Recife, in the state of Pernambuco, in northeastern Brazil, into a family of the professional middle class. His father, Alfredo, taught economics, while his mother came from the plantation-owning elite. He went to the American Baptist College in Recife, and was converted to Protestantism – for a short time. To complete his studies his family sent him to the United States, first to Baylor University in Waco (1918–20), and then to the Faculty of Political Science at Columbia (1921–22). Returning to Recife in 1923, he remained there for the rest of his long life, apart from a brief exile, in 1930, and visits to Europe, the United States, Latin America, and, in 1951–22, at the invitation of António Salazar, to Goa and the Portuguese colonies in Africa.

Freyre would have hated to be called a 'social scientist.' In his own eyes he was a man of letters, who published poems and two 'seminovels,' although he usually wrote nonfiction. He was not a professional academic, although he held several appointments as a visiting professor both in Brazil and in the United States, at Stanford in 1931, at the University of Michigan in 1939, and at the University of Indiana in 1944, where he offered a general interpretation of Brazil (Freyre, 1945a). He preferred freedom and leisure to a permanent post in a university and supported himself and his family mainly by writing for (and sometimes editing) newspapers, especially the *Díario de Pernambuco* and *A Provincia* (both published in Recife) and *O Cruzeiro*, the most important Brazilian weekly in the 1950s.

Freyre was a public intellectual, involved in politics. From 1926 to 1930, he was cabinet secretary to the governor of Pernambuco, Estácio Coimbra, and went into exile with him after the revolution of 1930 that brought Getúlio Vargas to power. From 1946 to 1950, he was a deputy in the Constituent Assembly, his party being the National Democratic Union that opposed the Vargas regime. He was denounced as a Communist and described himself as opposed to anti-Communism. However, in 1964, Freyre came out in support of the military coup of 31 March, thus losing some old friends. Thus, his political position, difficult to define, veered between radical (or as he would say, 'anarchist') and conservative.

Freyre was a polymath who wrote about art, literature, current affairs, the social sciences, and, above all, social and cultural history. He was an eclectic thinker, soaking up ideas like a sponge, and an omnivorous reader, both of literature (especially English literature) and the social sciences, beginning when he was young and keeping up with new developments until his 70s. He was also an active reader, turning down pages, underlining and writing in the margins of his books. The books that he discussed and annotated most carefully provide valuable clues to his development and to the approaches to the social sciences that interested him the most (Burke and Pallares-Burke, 2008).

The books he read on the subject might be divided into three archaeological strata. In the first place, old books published before he became an adult. In sociology, these works included Auguste Comte, Herbert Spencer, Frédéric Le Play, Gabriel Tarde, Emile Durkheim, Georg Simmel (whose essayistic approach he found appealing), Thorstein Veblen (whom he described as a social scientist 'with a scientific and even a poetic imagination') on the leisure class, and Max Weber on the Protestant ethic. In geography, Friedrich Ratzel, Paul Vidal de la Blache, Jean Brunhes, Ellen Semple, and Ellsworth Huntington. In anthropology, Edward Tylor and Alfred Haddon, Bronisław Malinowski, Marcel Mauss, and the early work of Franz Boas. In psychology, Wilhelm Wundt, William James, Sigmund Freud, and Havelock Ellis. More important for his thinking than most of these social scientists, however, were the ideas of John Ruskin, William Morris, and (on race mixture) the writer Lafcadio Hearn.

The second of the three strata was the work of Freyre's contemporaries: Robert Park, William Thomas, Gabriel Le Bras, and Georges Gurvitch, 'one of the most important sociologists of our time,' in sociology; Edward Evans-Pritchard in anthropology; Carl Sauer and Pierre Gourou in geography; and Gordon Allport in social psychology. In the last of the strata, one finds books by a younger generation: Clifford Geertz, Marshall Sahlins, R.D. Laing, Liam Hudson, Jean Duvignaud, and Alain Touraine.

In what follows, Freyre's studies of and his contributions to geography, psychology, anthropology, and, above all, sociology and history will be discussed discipline by discipline, followed by a more general assessment of his contribution to social and cultural theory.

Geography

Freyre was well read in geography. He discussed climatology and soil science on occasion but gave most attention to human geography, especially cultural regions and what Boas called their 'ecotypes' (Freyre was a Pernambucan patriot as well as interested in regionalism in general). The geographer who was most important for his work was Carl Sauer, whom he knew,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61199-6

and whose cultural and historical approaches resonated with his interest in the environment and its history, growing out of a concern, already expressed in the 1920s, for the 'devastation of the forest' in Brazil. Already visible in his best known work, *The Masters and the Slaves* (1933), this interest took center stage in *Nordeste* (1937), an essay in what the author called 'social ecology' that examined the effects of the concentration on the cultivation of sugarcane on the landscape, the animals and the people of his native region. What Freyre called 'the drama of monoculture' is emplotted as tragedy or as 'social pathology': the pollution of rivers, the poisoning of fish, and so on. *Nordeste* replaced what the author called the system of 'patriarchal economy' in its social and cultural contexts. This work, which has never been translated into English, is a small masterpiece.

Psychology

Freyre's eclecticism is perhaps most visible in his interest in and use of a variety of approaches to psychology, from William James via Gordon Allport to R.D. Laing. In the case of Allport, whom he met, it was the use of personal documents for the analysis of personality that most attracted Freyre, allowing him to engage in what would later be known as 'psychohistory.' Freyre often referred to psychoanalysis but was somewhat ambivalent about it, attracted to the explanatory system yet skeptical of its claims, whether made by Freud or Jung, Karen Horney or Erik Erikson. He criticized colleagues such as Artur Ramos for excessive fondness for psychoanalytical explanations and he gradually retreated from this approach himself. All the same, in the 1930s, Freyre interpreted the relations between masters (and mistresses) and their slaves in terms of sadomasochism. He emphasized what he called the 'psychoanalytical function' of confession and carnival, and noted 'the Brazilian inferiority complex.' He not infrequently remarked on split personalities, citing Robert Louis Stevenson's Dr Jekyll and Mr Hyde rather than the psychological literature. He described the rebel António Conselheiro as paranoid, and the bishop of Olinda (near Recife), Frei Vital, as 'sublimating' his love for his mother into his love for the Church.

Anthropology

Freyre's work was closer to anthropology than it was to either geography or psychology. He taught anthropology at the Escola Normal in Recife in the 1920s, and sometimes described himself as more of an anthropologist than a sociologist. He carried out something like fieldwork on Afro-Brazilians in his native Recife in the 1920s, paying particular attention to their material culture (the women's turbans, the men's pipes, the children's toys, and so on). He called Franz Boas his 'master' on the strength of having attended some of his lectures at Columbia, and he was familiar with the work of students of Boas, notably Ruth Benedict, Robert Lowie, and Melville Herskovits. In the case of Brazilian anthropology, he was an admirer of Edgar Roquette-Pinto and a friend of Heloísa Alberto Torres, René Ribeiro, Darcy Ribeiro, and the expatriate Frenchman Roger Bastide.

What difference did anthropology make to Freyre's achievement? He devoted only one of his many books to the subject, *Problemas brasileiros de antropologia* (1943), a collection of essays discussing both culture and race (while claiming that 'there are no races in an absolute sense'). However, the most important theory with which Freyre is associated, that of hybridity or mixture, discussed below, depends on his anthropological studies. Again, Freyre could hardly have written *The Masters and the Slaves*, especially the chapters on the culture of the Indians and the Africans, without a wide reading in anthropology, leading him to revalue Afro-Brazilian culture, generally dismissed by white intellectuals at that time, and to organize the Congress on Afro-Brazilian studies in Recife in 1934 (Levine, 1973). As for his shift from a concern with race to a concern with culture, discussed below, it owed much to Freyre's friend Rüdiger Bilden, who had studied with Boas; to Boas himself (especially to the famous article on 'Race' in the *Encyclopaedia of Social Sciences*), and to Roquette-Pinto. Again, the interest in material culture and everyday life that Freyre revealed in his historical studies, long before these topics became fashionable, like his concern for what he called 'microscopic history,' was inspired by both anthropology and by sociology.

Sociology

Of all the social sciences (unless they include history), the one to which Freyre was closest in practice was sociology. As a student, he took two sociology courses at Columbia with Franklin H. Giddings, and 6 years later he was teaching the same subject in Recife, and again, from 1935 to 1937, in Rio de Janeiro, in the new University of the Federal District, adopting a microsociological approach and recommending his students to begin by studying everyday life in the street in which they lived. He published a general textbook on sociology (1945b); an introduction to the sociology of medicine (1967); a *contribution to the sociology of biography* (1968); and, with characteristic ambivalence and egocentrism, an essay entitled *How and Why I am and am not a Sociologist* (also 1968).

In this domain as in others, Freyre's eclecticism is apparent, but his strong likes and dislikes are more visible than usual. He expressed enthusiasm for a wide range of sociologists. Among North Americans, he particularly appreciated the work of the Chicago school. Ernest Burgess was praised for his ecological approach to the city, along with the near-forgotten Indian sociologist Radhakamal Mukherjee, another 'master.' On the other hand, Freyre referred on occasion to the oversimplifications of American sociology, failed to mention Talcott Parsons (doubtless deliberately) and mocked Pitirim Sorokin for his ambition to be the 'Thomas Aquinas' of the discipline.

Among the Germans, one might speak of Freyre's elective affinity with Max Weber, going back to his brief flirtation with Protestantism. He was fascinated by what he sometimes called 'Protestant civilization,' as exemplified by punctuality, for instance, by diary keeping (a substitute for Catholic confession) and by an ascetic style of cooking. Freyre did not always agree with Weber (he criticized the Protestant ethic, for instance), but he treated Weber as an interlocutor even when

he did not mention his name, sharing his interest in patrimonialism, the relation between the public and the private, and the idea of time as money.

Freyre's extremely individual approach to the discipline is at its clearest in *Sociology* (1945b), which was planned as a textbook, thus giving the author both the need and the opportunity to comment on the development of the discipline. The text may even have been used as a textbook, since it went through four editions, but it is better described as a long essay (originally 772 pages, expanded later), criticizing claims made for sociology and discussing its relations with neighboring disciplines rather than introducing students to the subject. Freyre denounced what he called sociological 'purity,' declared that Proust had portrayed the French aristocracy more successfully than all the disciples of Durkheim, and called for a triple approach that would combine sociology with psychology and with history. His discussion was supported and enlivened by many Brazilian examples, for the most part repeating points that the author had already made in two historical studies, *The Masters and the Slaves* and *The Mansions and the Shanties* (1936) or would make in a third, *Order and Progress* (1959).

History

Freyre was and is most famous as a social historian (Hanke, 1939; Briggs, 1981). From the early 1920s, he declared his ambition to write the kind of history that would include the people as well as political or military leaders, women as well as men and children as well as adults (he planned to write a history of childhood in Brazil). It is no surprise that he was drawn to the American 'New History,' to the *Annales* School in France (describing Marc Bloch and Lucien Febvre as 'masters') and to the *English Social History* of George M. Trevelyan (he filled the margins of his copy with annotations).

Freyre practiced what he liked to call 'intimate history,' a study of ordinary people, humble objects, and apparently trivial but significant details. This project has of course enlisted many recruits since the 1980s under the banner of the 'new cultural history,' but in Freyre's time it was still relatively unusual, if not eccentric. He studied what he called 'culture,' or 'civilization' in a broad, anthropological sense of those terms, writing, for instance, about the 'sugar civilization' of Pernambuco or the 'carboniferous civilization' of Britain in the age of the Industrial Revolution.

Freyre's interest in cultural encounters and exchanges, including 'transculturation' (which he described as "the excellent neologism of Professor Fernando Ortiz"), can be found in many of his writings but it is particularly clear in *The English in Brazil* (1948), where, discussing the fashion for English goods among the upper classes of early nineteenth-century Brazil, he speaks not only of cultural imperialism but also of active reception, domestication, and on occasion of reverse acculturation, of Englishmen who adopted a Brazilian style of life.

However, Freyre is best known for the trilogy in which he traced the social and cultural history of Brazil from 1500 to 1900, with special emphasis on the patriarchal family (Tannenbaum, 1963). The first volume, covering the first three centuries, focused on the countryside, and in particular on the sugar plantations of the Northeast, arguing that the particular form of culture and society that developed in that region exercised a decisive influence on the rest of Brazil and also on later centuries. The second volume shifted to the cities of Brazil in the early nineteenth century, especially Rio, Salvador and Recife, while the third volume was concerned with the late nineteenth and early twentieth centuries.

The trilogy is remarkable in a number of respects. It was brilliantly written, especially the first two volumes. Indeed, Freyre was one of the most important Brazilian writers of the first half of the twentieth century, one of the first to abandon formality and to write in a manner that was close to colloquial Portuguese in both vocabulary and syntax. He was a master of vivid metaphors and he appealed to his readers with what he called a 'sensuous history' that reconstructed not only the look of the past but also its sounds (church bells, street cries), its smells (including urine and semen), its tastes (such as water drunk from an earthenware jar), and even touch (the practice of *cafuné*, stroking someone's hair and removing the lice). The three volumes were 'impressionist' in the sense of producing their effect by a succession of vivid vignettes and memorable anecdotes, describing rather than analyzing and using personal documents more often than statistics.

The first volume of the trilogy caused something of a sensation for its choice of topics; one of the chapters of *The Masters and the Slaves* bears the title, in its English translation, of 'The negro in the sexual and family life of the Brazilian' (it is difficult to know whether it was the reference to race or sex that readers found more shocking in 1933). To organize the material of the first volume, Freyre had the brilliant idea of focusing on the house as a microcosm of society; literally translated, the title of the book would be *The Big House and the Slave Quarters*. In similar fashion, the second volume focused on the *sobrado*, the town house of the rich, and the *mucambo* or shack, the ancestor of today's *favelas*, although it also had much to say about the street as an arena for work and play alike. It is in this second volume that Freyre made most use of what he had learned from Veblen, essentially the idea of conspicuous consumption as a way of affirming or maintaining social status. Like its predecessors, the third volume discusses types of building (notably the hotel) as symbols of society, but its most original feature is its method. The main source that Freyre used in *Order and Progress* was a questionnaire about social attitudes (including 'the heroes of your childhood') and memories of everyday life (toys, dances, fashions, and so on) addressed to survivors from the period, a 1000 people born between 1850 and 1900. About 20% of them responded (for a critique of this volume, see Skidmore, 1963–1964). This original and ambitious work of history was also the principal vehicle for Freyre's social and cultural theory.

Theory

Freyre's late essays on futurology, urbanization, and other topics of contemporary interest lack the richness and density of his earlier work. It was in his studies of social history that he made his most important contribution to theory. A central concept in Freyre's work was that of equilibrium. However, he imagined this equilibrium not as static but dynamic, an

'equilibrium of antagonisms' (an idea that he learned from Herbert Spencer and Franklin Giddings). He has often been accused of having too rosy a picture of Brazil, of over-emphasizing harmony. This may well be the case, but it should be added that he did not deny the existence of conflict. What he suggested was that conflicts could be and sometimes were harmonized or to use one of his favorite words, 'softened.'

Related to this process of softening is the best known theory associated with Freyre: the theory of hybridity, in the sense of miscegenation and also of what he often called the 'interpenetration' of cultures (Needell, 1995; Cleary, no date). In *The Masters and the Slaves*, he argued that this interpenetration was beneficent and that it had made Brazil what it was, writing that "Every Brazilian, even the light-skinned fair one, carries about with him on his soul, when not on soul and body alike … the shadow, or at least the birthmark of the Indian or the African" (1933: p. 278). It was this argument in particular that made him famous. In the 1930s, the people, or at least the intellectuals, were anxious about the Brazilian's apparent lack of identity. Since they were descended from a mixture of the indigenous inhabitants of the country, European immigrants (mainly Portuguese), and African slaves, what could they be?

Educated Brazilians tended to believe that interbreeding led to degeneration and that the only hope for the country lay in its 'whitening,' thanks to a new wave of immigration from Europe. Freyre himself believed this for a time, but he reversed his position to claim that mixture was not an obstacle to Brazilian identity, it was the identity. He owed this conversion to his friend Rüdiger Bilden, who had studied with Franz Boas; to Boas himself, whom he adopted as a 'master' (displaying a photograph of Boas in his study); and to the Brazilian anthropologist Roquette-Pinto (Pallares-Burke, 2005, 2012).

Freyre saw miscegenation as a key to Brazilian history, associating it with a regime of slavery that was, in its patriarchal, paternalist way, more gentle than slave regimes elsewhere. This point was a relative one; he was well aware of the violence built into the system. On the other hand, he paid little attention to the fact that miscegenation was generally asymmetrical, the result of relations between upper class white males and black female slaves. He has also been criticized for his rosy picture of what is often called 'racial democracy,' in other words the lack of racism in Brazil (Guimarães, 2005). Once again, his point was a relative one; Brazilians, he argued, came nearer to this ideal than most if not all other cultures. Later studies (including one by Fernando Henrique Cardoso in his days as a sociologist) focused on discrimination in cities in the south of Brazil and undermined Freyre's argument, although it appeared and indeed still appears more plausible in the region he knew best, the Northeast, than it does elsewhere.

The Masters and the Slaves also discussed cultural mixing or hybridization (in Portuguese, *mestiçagem*) in domains that range from vernacular architecture to language, clothes, and cuisine. At a time when sociolinguistics was in its infancy, and had not yet been christened, Freyre wrote brilliant pages describing the influence of Africa, and especially of African slave nannies, on the vocabulary and even the accent of upper class Brazilians (another striking example of reverse acculturation).

In later works, Freyre returned to the concept of *mestiçagem*, to play with it or as he might say to dance with it, pushing it to see how far it would go. Thus, he extended the concept to sport, writing about 'mulatto football,' for instance, not only as a game played by mulattos but also as a sport that mixed English football with the Brazilian tradition of *capoeira*. He extended it to literature, describing the novels of his friends João Lins do Rego and Jorge Amado as hybrids of fiction, social history, and folklore. He extended the idea to the practice of sociology, which he viewed as a mixture of art and science, a discipline that was 'amphibious' or 'polytheist.' He extended the concept of *mestiçagem* to politics, especially to Brazilian politics during the transition from empire to republic, or more exactly, so he suggested, from a republican form of empire to an imperial form of republic. He even extended the concept to sex, allowing a character in his 'seminovel' *Mother and Son* to suggest that people of hybrid gender sometimes realize themselves more fully than the pure do.

The idea of *mestiçagem* underlies what may well be Freyre's most important contribution to the social sciences, his frequently reiterated suggestion that their evidential base, essentially Western Europe and the United States was too narrow, and that generalizations about human culture and society needed to draw on the experiences of other parts of the world. In a word, a word that Freyre liked to use, the social sciences needed to be 'tropicalized.' For example, Freyre wanted to see a tropical sociology on the analogy of tropical medicine, or even an interdisciplinary 'tropicology.' In short, he advocated what is now called 'Southern Theory' long before it was christened.

Linked to the idea of tropicalization is Freyre's least successful contribution to social theory, the concept of 'Luso-Tropicalism,' according to which the Portuguese were better adapted than other Europeans to building an empire in the tropics because they were accustomed to miscegenation and cultural mixture at home, thanks to the Arab invasion of Iberia in the Middle Ages. This argument appealed to the Salazar regime in Portugal at a time when their colonies were becoming restive, and Freyre was invited to pay an official visit to 'Ultramar,' in other words the Portuguese possessions in Africa and Asia, in 1951.

One criticism of the idea of tropicalization is that it offers a binary opposition, between tropical and temperate, at the expense of many possible nuances. As the titles of some of his books suggest – *The Masters and the Slaves*, *The Mansions and the Shanties*, *Adventure and Routine*, and so on – Freyre was fascinated by polarities, although he also liked to undermine them by examining connections, exchanges, and hybridization. Two of these polarities reverberate throughout much of his work: Jekyll and Hyde, and Apollo and Dionysus. He used Robert Louis Stevenson's 'Dr Jekyll' and 'Mr Hyde' as a means to move away from a vision of history as a conflict between heroes and villains, arguing that in the case of Getúlio Vargas, for instance, this conflict took place within the President's personality and policies. As for the opposition between the Apollonian and the Dionysian, Freyre borrowed it, with acknowledgments, from Ruth Benedict (although he had read Nietzsche for himself) and made use of it again and again. English football, for instance, was described as Apollonian, while Brazilian football was Dionysian. Intellectuals, and more specifically social scientists, were divided in similar fashion, sociological purists being labeled as Apollonian while Freyre himself was Dionysian.

Reception

The reception of Freyre's books in Brazil has passed through three main phases. Despite criticisms of *Casa Grande* in some quarters, it quickly became both a sociological and a literary classic, while its author was treated as a 'master' (among others, by the novelist Jorge Amado). However, the criticisms made of Freyre's work by the sociologists of São Paulo diminished Freyre's reputation, which was also undermined, at least among intellectuals of the left, by his accepting the official invitation to Ultramar in 1951, thus implicitly accepting the use of his work to legitimate a decaying colonial regime. His support for the military coup in Brazil in 1964 blackened his image still more, and in some universities, students were advised by their teachers not to read his work. Following the reestablishment of democracy in Brazil in the 1980s, Freyre's star began to rise again. Some leading figures in the social sciences in Brazil, notably the anthropologist Roberto DaMatta, work in what might be called a Freyrean tradition. Freyre also enjoyed success at a popular level of a kind rarely attained by a social scientist, since some of his books were translated into plays, films for the cinema and television, and even a comic strip. More recently, when Rio was selected to host the 2016 Olympics, President Lula's speech, describing Brazilians as "a mixed people and a people that like to be mixed," sounded like a summary of the central thesis of *Casa Grande*.

Abroad, Freyre was launched by the North Americans and the French. His lectures at Bloomington in 1944 helped make him known in academic circles in the United States, and his trilogy on Brazilian history was published in translation between 1946 and 1970. In the case of France, the historian Fernand Braudel discovered Freyre's work while he was teaching in Brazil in the late 1930s, and later published an enthusiastic review of it (Braudel, 1943). Braudel's colleague Lucien Febvre wrote a preface to the French translation of *Casa Grande*, and Braudel did the same for the Italian translation. Praise from Roger Bastide, Roland Barthes, Jean Duvignaud, and Georges Balandier also helped Freyre's work to circulate in France. His reputation in Europe was probably at its height in the 1950s, but translations of his books still appear from time to time, into Hungarian, for instance, and Japanese.

Conclusion

Among the social scientists of his day, Freyre stands out as a southern theorist, as a man of letters turned anthropologist and sociologist, and as a scholar who insisted on the need for students of culture and society to learn from both history and literature. He lived long enough to see the humanistic approach to the social sciences that he always advocated come back into fashion. Preferring ethnography or 'microsociology' to quantification, and insisting that social scientists avoid specialized jargon, it might be said that Freyre was closer to the generations before and after him than he was to his own and even that his attachment to tradition helped him to become an innovator.

Abstract

Friendship has frequently been juxtaposed to the relationships that constitute the 'structuring structures' of social life, be they the kin and descent relations of small-scale societies or the institutionalized forms of modernity. But interest in friendship and related concepts (mutuality, trust, intimacy, love) has increased dramatically in recent decades. The processes of globalization and postclassical trends in social theory are equally implicated in the increasing relevance of friendship to both ethnographic inquiry and theoretical concerns. Nevertheless, for anthropologists, friendship and kinship remain connected in ethnographically, theoretically, and conceptually unsettling ways.

Introduction

It seems obvious that the significance of friendship to general social life varies across time and space. However, the classification of the empirical characteristics of friendship has not been simple, even for scholars of Western society (Pahl, 2000); anthropologists, who consider friendship in a comparative perspective in which empirical and conceptual issues intersect, also note the refractory nature of the topic (Paine, 1974; Firth, 1999; Coleman, 2010).

The anthropology of any topic must avoid the twin dangers of a specificity that inhibits generalization or comparison and an analytically useless generality, but there are additional factors that make the anthropology of friendship an exacting area of inquiry. First, the philosophical roots of the social sciences include influential treatises on friendship by (among others) Aristotle, whose writings on the topic continue to inform many discussions, notwithstanding the conflict between his orientation and the dominant traditions in social theory, which have found the constitutive role of biographical particularity in friendship hard to integrate. More conspicuously, the very concept of friendship implicates one or more ethically rich, affect-laden notions (such as love, intimacy, trust, loyalty, sincerity, and equality) as do certain more experience-distant counterparts of those notions ('social capital,' 'ontological security,' for example). Moreover, anthropologists interested in friendship have worried that the very identification of a friendship involves the observer in the inner motivational states of social agents. So, while friends may be crucial to the agent's lived experience, scholars of social structure appear to have reason to ignore friendship, despite its empirical entanglement with significant politico-economic phenomena (exchange and alliance). Accordingly, complex issues can arise in ethnographic investigations of friendship no less than in cross-cultural comparisons or consideration of its relations to cognate phenomena (kinship, bond friendship, blood brotherhood, *compadrazgo*, and other patron–client relations).

Additionally, friendship has remained a shadowy region of the theoretical landscape because of the light shed by anthropologists on kinship and familial relations – the classical 'structuring structures' of so many ways of life. More recently, however, the conceptualization of friendship has been complicated by three interconnected factors: first, the globalization of cultural elements of Western modernity, in association with the consolidation of capitalism's global economic power, has produced complex hybrid localities whose ethnographic descriptions are difficult and theoretically contested; second, these same currents have increased the tendency of Western subjects to understand themselves as post-traditional, self-fashioning beings, sensitized to the work of gender, class, and racial stereotypes; third, the last 40 years have seen the confrontation/complication of structural approaches through an emphasis on agency and its specificities with respect to power, gender, and historical process (including factors that are contingent with respect to all preexisting local characteristics).

These trends do not, however, imply that there are great discontinuities in scholarly approaches to friendship. It must still be defined by contrast with other relations in a multidimensional space that sets up the possibilities for the various dyadic and polyadic links between ego and others, including those that form the developmental context of persons. The axes that best define the personal and institutional possibilities of that space are, in truth, essentially contested aspects of social theory; but key features of friendship (its 'private nature,' 'voluntarism' and 'individualism') mean that it has in large part been constituted by its juxtaposition with, on the one hand, the affective but 'obligatory' relations of the kin domain, and, on the other, those impersonal relations that constitute the broader institutional order of modernity.

A remark concerning the scope of this contribution: recent work in the broad area of the anthropology of friendship has come from two quite different directions: evolutionary theory, most conspicuously in Hruschka's (2010) large-scale comparative investigation of friendship (augmented by test data and a broad sampling of ethnographic literature); and from a socio–cultural anthropology enlivened, to various degrees, by the advent of 'new kinship studies' and the anthropology of personhood, as well as by the challenge of dealing analytically with the entanglement of local socio–cultural settings and global flows. While these two strands of scholarship are inspired by very different commitments, there is much about friendship upon which they agree: the ubiquity and variability of friendship; its significance in organizing important socio–economic relationships within and between culturally

defined networks; the role of positive affect in paradigm cases of friendship, even those that are organized with respect to explicit norms or are referable to instrumental values; the centrality to paradigm friendships of generalized reciprocity (sharing or mutuality) rather than balanced reciprocity. These two streams also converge because conceptual issues concerning altruism, egoism, and what is involved – in several different senses – in a person's doing something for the sake of another, arise in evolutionary and social theory alike. This entry must nevertheless concern itself with the reconfigured interest in friendship in socio–cultural anthropology.

Finally, we can only mention in passing the extensive literature on friendship in sociology, psychology, and gender studies. It must suffice for us to stress that the configuration of empirical, theoretical, and conceptual issues that characterizes anthropological discussions of friendship are quite general (Adams and Allan, 1998; Pahl, 2002).

Terms

The word 'friendship' needs some preliminary attention: it can refer either to the relationship between persons ("Their friendship is of long standing"), or to the inclinations, dispositions, and actions of a single person ("She assured him of her friendship"), in which case it is roughly synonymous with 'friendliness'; of course, these are intimately connected, but we focus on the relationship between friends, for friendly sentiments can be unreciprocated, while a friendship necessarily involves mutuality.

Although anthropologists can rarely ignore issues of translation, their usual concerns about lexical and conceptual equivalents across languages are, in the case of 'friendship,' compounded by the continuing influence of classical sources – most notably, Aristotle, in whose treatises on ethics much of the academic discussion on the subject still finds its source. The Greek term (*philia*) usually translated as 'friendship' approximates the English notion of (nonerotic) love and encompasses family members. Indeed, the term 'friend' itself derives from an old Germanic verb meaning 'to love,' and the noun's cognates in certain northern European languages continue to designate kin rather than friends. Yet the semantics of contemporary English, at least, offer no impediment to a description of, say, a sibling as a mortal enemy; similarly, one's jailer or bank manager may be counted a friend. In many small-scale settings, by contrast, social life is such that ego's total social field and ego's kindred are isomorphic, so that those an English speaker would count as ego's 'friends' necessarily represent a subset of his or her relatives.

The general point here is not just that attention to linguistic or conceptual detail is advisable, but also that difference and change with respect to configurations of friendship involve ethical, linguistic, and social norms and the relationships between them. For example, a principal issue in the analysis of friendship (and its cognates) has always been the extent to which relations that involve very different configurations of affect, degrees of 'utilitarian' motivation or 'choice' and power differentials, or which subsist in highly contrasting social formations, can be brought under a single, analytically significant category. The conceptual issues here seem tailor-made for a scholar like Derrida (1997), with his nose for 'undecidability' and 'aporetic structures'; as he evidently appreciates, these issues are connected to taxing issues in other areas of anthropology (like the gift).

These issues notwithstanding, we follow Aristotle's line in taking paradigmatic friends to be those who enjoy one another's goodwill, trust, and affection; they share these things and – crucially – each not only knows this of the relationship, but also knows that the other knows it; this suite of interconnected characteristics means that friends can count on or trust one another, which thereby becomes relevant to their actions and strategies. Friendship, then, is sensitive to time and the interpersonal experiences of those involved, which helps to explain the organic images and metaphors often used to characterize it.

Friendship and Anthropology

Many discussions of this topic begin by pointing out that friendship has not loomed large within anthropology. In a discipline that grew to maturity through its engagement with the different ways in which kin relations permeated, organized, or regulated social structures, friendship has been easy to overlook, even if its universal presence and general significance has been acknowledged (Leyton, 1974; Firth, 1999). More recently, anthropologists (and sociologists) have grown more interested in the specificities of friendship; but by the time its claims to attention became less residual, the emphasis on personhood and its cultural construction that had come to dominate post-Schneiderian kinship theory ensured that friendship once again had to accommodate itself to an environment already occupied. Accordingly, Coleman's view that classical anthropological studies of friendship are "few and far between" (Coleman, 2010: p. 197) is apt.

Yet, a picture of general neglect is a distortion: certain topics and the organization of certain classical small-scale societies necessitated a consideration of interpersonal relations forged, and often formally recognized, between friendly individuals unrelated by primary identities (for example, Evans-Pritchard, 1933; Firth, 1936). Moreover, students of peasant communities, proletarian urban networks, and other politically encompassed social settings made sure that friendship and other informal, private social relationships were given analytic space (for example, Whyte, 1943; Mintz and Wolf, 1950; Hart, 1973). In addition, for much of their history, anthropology and sociology shared sources of inspiration, research agendas, and range of theoretical orientations. Accordingly, a background awareness that the significance of friendship in social networks was an empirical cultural variable was common among anthropologists too; indeed, it was sometimes stressed by those interested in developing transactionalist alternatives to structuralism, or in refining functionalism (Eisenstadt, 1956; Paine, 1969; Boissevain, 1974).

When friendship was considered in a comparative perspective, it was usually in an institutionalized, often ritualized, form, or as it shaded into patron–client and comparable inegalitarian relations. This is not very surprising, given the predominant twentieth century views on interpersonal

relations and social order. General theoretical commitments, which stressed the externality and coercive power of social facts, could hardly avoid marginalizing informal, personal relationships. So, while friendship was never ignored, it was often considered to constitute a residual category, comprising phenomena seen as peripheral or interstitial, especially with respect to kinship and descent and other institutional orders. Friendship, it seemed, challenged even the most muscular of social theories: neither the invocation of rules or custom nor the elucidation of useful effects sufficed to account for actual behavior between friends (Paine, 1969, 1974; Pitt-Rivers, 1968). On the other hand, many scholars underlined the 'always already' cultural nature of human agents, and stressed the social homophily of friendship (with respect to class, gender, age, and other aspects of identity).

Studies of friendship were no less affected by interests in agency and by feminist theory and critique than other aspects of the social sciences. Students of friendship, in fact, may have been especially susceptible to feminist critique, for gendered stereotypes about the capacity for making friends, commitment to domestic spaces and to familial values were an important part of many cultures, including that of most social scientists. In anthropology, this predicament was compounded by the prevalence of the Mediterranean and Latin America in the ethnography of friendship, regions where gender stereotypes are conspicuously relevant to relationship patterns (Uhl, 1991).

Volumes dedicated to friendship that have been published recently (Bell and Coleman, 1999; Schmitt et al., 2007; Desai and Killick, 2010), and several theoretically motivated articles (e.g., Killick, 2009; Fausto, 2012) seek to bring friendship closer to the center stage of anthropology. They take account of the scope of global cultural flows as well as the transformation of social theory, and show how, once questions about the effects of globalization on local patterns of sociality became an explicit research topic, the question of friendship became salient. Interestingly, in such settings, both kinship and friendship contrast with the impersonal relations that constitute state and international institutions: although they are personal, relatively private aspects of social life, they are nevertheless crucial to the networks that define local political economies (including those that are part of diasporic networks). If kinship and friendship are similar in these respects, the constructionist and 'performative' orientations inspiring the 'new kinship studies,' also weakens the contrast between them. However, this has been subject to considerable discussion and controversy.

Friendship also evokes those Maussian lessons on the role of exchange in forging links between individuals and groups that were central to twentieth-century anthropology's understanding of social relations. Sahlins' oft-repeated chiasmus generalizes the point: "If friends make gifts, gifts make friends." These Maussian insights have been challenged by more recent anthropological models of relatedness as radically generalized: if relationships are performed in accord with local constructions of personhood, practices predicated of interactions between folks related as kin and those related as friends become less important. This trend finds clear expression in a recent exposition from Sahlins, which endorses Aristotle on the *friend* as 'another self,' but as part of a wide-ranging case for seeing *kin* as "persons who are members of one another, who participate intrinsically in each other's existence" (Sahlins, 2011a: p. 2). This is not so remarkable, since Aristotle saw relations between close kin as paradigms of the love (*philia*) that characterized true friendship. Yet Sahlins' conflation, while consistent with currently dominant views on relatedness in the anthropology of kinship, does raise concerns about the advisability of eliding distinctions between kinds of relatedness, and not only because such distinction are often crucial to those we study; after all, these differences are, *prima facie*, of existential no less than sociological importance. Recent objections by specialists to the annexation of friendship to an expanded notion of 'relatedness' (discussed below) raise the problem explicitly, but these relate to matters that have been crucial to the theoretical characterization of relationships since the advent of the social sciences.

Friendship, Kinship, and Difference in Cultures of Relatedness

At least since "the first book-length study of friendship in modern anthropology" (Leyton, 1974), scholars have spoken of the need to maintain an open, 'exploratory' orientation to the topic. This need arose because of the crosscutting articulation of 'psychological' and 'social situational' levels on which friendship operated. In Paine's terms ([1970]1974: p. 1), the stark juxtaposition friendship made apparent between the 'moral utilitarian and the social functional' approaches to social relations tended to raise doubts about how comprehensive the latter could be as social theory. Paine's use of categories that evoke Talcott Parsons' theoretical edifice (in particular, its 'pattern variables') is typical of the theoretical currents of the times; Paine (1974: p. 12) deemed functionalist theory appropriate to 'particularistic, solidary' groups classically studied by anthropologists, but wondered whether, in contemporary society, the prevalence of 'universalistic' relations and values meant that Simmel and Goffman would be better sources of understanding. The basic issue here is the difference between friendship and kinship as the latter was depicted in the structural-functionalist readings of 'traditional societies,' especially those to which descent theory had been applied so extensively and apparently fruitfully.

Space precludes a comprehensive genealogy of anthropological conceptions of kinship as these are relevant to friendship, but it would entail a consideration of, on the one hand, the characterization of those socio-political structures whose reproduction underpins the transgenerational identity of culturally defined populations (the "political-jural" realm, as Fortes (1969) famously designated it) and, on the other, the affective, morally charged arena of primary interpersonal relations within which ego, as a cultural being, acquires specificity, which – again, according to Fortes – is governed by 'the axiom of prescriptive altruism.' We can, though, sketch the interconnections here with a brief look at a text that has been much referred to (not always fairly), even in the most recent anthropological discussions of friendship: Pitt-Rivers' (1973) 'The Kith and the Kin,' written for 'The Character of Kinship,' a *festschrift* for Meyer Fortes. This and other works by Pitt-Rivers engage Fortes on kinship and its

fundamental character, but from the perspective of an Andalusian community, in which friendship is both socially fundamental and existentially problematic.

Pitt-Rivers paper begins by remarking the oddness of Fortes having chosen 'amity,' derived from the French term for 'friendship,' to designate 'the axiom of prescriptive altruism,' which Fortes claimed as central to kinship. It seemed that Fortes had "chosen to define the essence of kinship by appealing to the very concept of what it is not" (1973: p. 90). For, Pitt-Rivers continues, most scholars oppose kinship, as "inflexible, involuntary, immutable, established by birth and subject to the pressures of 'the political-jural domain' … [to] friendship, … which is its contrary in each of these respects" (p. 90). He delicately analyses his teacher's Aristotelian inclination to see amity as intrinsic to the child's experience of familial relations, as having their own moral values (beyond self-interest and egoistic calculation), while retaining the structural-functionalist's commitment to the prescriptions of the social order that bind behavior and sentiment. Pitt-Rivers seems to suggest (but not state) that Fortes' refusal to deal with the tension that his bifurcation of kinship (into a realm governed by primordial altruistic sentiments and a broader political–jural order grounded in rules) is unsustainable. For his own purposes, though, Pitt-Rivers is clear that friendship should be assimilated to the primordial/familial order of kin relations: as both involve the submersion of self-interest "*for the sake of* someone else" (p. 90; – his italics), and both are dimensions of the realm of sentiment (he says several times that 'the heart' must rule in these relationships), truly moral values, and of "the extension of the self" (p. 91).

Pitt-Rivers remains equivocal (or excessively delicate) about revising his teacher's perspective. He sometimes seems to endorse Fortes' suggestion that it is the behavior that matters, not whether it is motivated by nonjural sentiments rather than jural norms; for example, he suggests – by contrast to his stress elsewhere on the heart and its uncoerced inclinations – that amity can result from moral *obligation*. He underlines the difficulties caused by the fact that "the state of the heart … cannot be known for sure" (p. 98). At other times, by contrast, he stresses the "antithesis between the notions of jural and moral relations" (p. 96), and the requirement that amity remain "*purely* moral … untrammelled by the jural domain …" (p. 102; – his emphasis).

Yet the careful analysis that Pitt-Rivers offers in this rumination on Fortes' work gently but definitely underlines the tensions in Fortes' conception of kin relations and their relation to altruism. Indeed, the reader is sometimes struck by the thought that Pitt-Rivers aims to suggest that his esteemed teacher's key concept of 'prescriptive altruism' embodies a contradiction: an act that is performed because it is required by a social rule is not altruistic, since the heart's inclinations are trumped by jural requirements no matter what.

Pitt-Rivers (1954), in his earlier ethnographic analysis of an Andalusian village (for which Evans-Pritchard wrote the foreword), had already had occasion to ponder the epistemic difficulties of friendship – of telling when it truly sprang from the heart. He worried that the criterion that "distinguished true from false friendship flees from the anthropologist into the realms of motive" (p. 139). Interestingly, Paine cites this passage in each of his three pieces on friendship.

The stresses generated by the question of the role of motivations in intimate social relations have appeared elsewhere: Marshall (1977), worrying along similar lines to Pitt-Rivers, but under provocation from David Schneider's writings on kinship, also concluded that motivations, in the form of commitments (to kin *and* friends) to share and thereby maintain what he calls "intensive interpersonal relationships," had to be counted as central to the relations sustaining Trukese society.

Paine, like Pitt-Rivers, underlines the trust and affectivity that friendship involves, and the dangers of miscalculation or betrayal that these entail in many social settings. But, for the Western middle class, friendship choices are rendered less hazardous – on the whole – by their interstitial nature relative to market and bureaucratic relationships; friendships carry less political and economic weight than other relationships, so that friends are free to explore the possibility of attaining 'ideal' relations (1969). His later essay (1999) moderates this picture somewhat: the ideal values associated with modern friendship presuppose relations between persons, each of whom has 'verifiable self'; but this makes for vulnerability too, either through the friend's intent to deceive or because of the friend's self-deception. Here, Paine seems to return to Aristotle's view about that personal virtues of friends determines the degree of perfection of the relationship between them (Pakaluk, 1998); but it is evident that he still sees these personal virtues as somehow tangential to the "rights and obligations that are developmentally prior to … friendship and are conceived as indispensable to the proper functioning of the society" (1969: p. 508). Paine's later reflections offer a picture of Western friendship similar to that which he gave 30 years earlier: "a kind of institutionalized non-institution" (1969: p. 514) the understanding of which depended upon blending the structuralist's concern with rules with the Goffmanesque transactionalist's "discernment of ploys or strategies" (1974: p. 13).

Reference to Paine and Pitt-Rivers's work readily evokes the influential Allan Silver (1989, 1990, 1997, 2003) and his careful, historically informed work on models of friendship in various strands of social science theory. Silver endorses Paine's (1969) observations about the specificity of contemporary friendship and draws many threads together to demonstrate how historically specific were the nineteenth-century oppositions to which most later social theory was heir. Although, he argues, the juxtaposition of personal, private, moral, and intimate modes of sociality to impersonal, public, commercial, and formal modes runs together different and independent sociological parameters, it fits with certain orientations to nineteenth-century Europe's past, common to radicals no less than conservatives. This dichotomous picture came to represent the historical (and teleological) transition to modernity, thereby (and in addition) serving as the basis for societal typologies.

On this view, friendships under modernity are stereotypically "voluntary, unspecialized, informal and private … grounded in open-ended commitments without explicit provision for their termination" (1989: p. 274). As such, friendship is exemplary of "the private domain of personal life" (1997: p. 46) and diametrically opposed to the contractual, public, and impersonal foundations of modernity's diacritical institutions. But, Silver argues, with a wealth of evidence from literature, "that this domain of the private, however suffused with

historical imagery, is less a historical survival than a distinctive creation of the impersonal order central to modern economies and polities" (1997: p. 44). Indeed, the leading figures of the eighteenth-century Scottish Enlightenment (Smith, Hume, Ferguson) confound the presentism of later social theorists in espousing a liberalism that celebrates commercial society's ability to partition self-interested relations from those grounded in moral sentiments (1990); commerce actually made room for purer, more sincere, friendships.

In turn, James Carrier's (1999) provocative essay on friendship and personhood, in Bell & Coleman's important volume, extends Silver's line of argument: he begins by contrasting contemporary Western views about friendship, as "based on spontaneous and unconstrained sentiment" (1999: p. 21), with relations grounded in "the demands or expectations placed upon them by the ties of kinship, trade, propinquity, interest or the like" (pp. 22, 23). This notion of friendship "entails a distinct conception of what people are like, of the self" (p. 23). Then, through an account of the history of that conception of self, and a contrast between it and the Melanesian self as discussed in seminal anthropological accounts, Carrier suggests that "the terms by which Westerners distinguish friendship from other sorts of relationships" are not available to Melanesians who sort relations by reference to kinship and to social situatedness (p. 31). Finally, Carrier draws attention to a point repeatedly underlined by sociologists of friendship (Adams and Allan, 1998; Pahl, 2000), that Westerners' pretheoretical intuitions about friendship, its moral qualities, and what it entails or permits in the way of behavior, is very much a function of time and place (p. 36), even controlling for such factors as class or age. In the context of the debates occasioned by the juxtaposition of Melanesian dividuality and Western individuality, which has been prominent in discussions of the relationship between kinship and personhood for two decades, Carrier's analysis seems to have implications that he forbears to state: that Melanesian views of the person contrast with those of some Westerners much more than with others. He discusses sociological research showing that commitment to individualism in the West varies in important ways with gender (pp. 31, 32), class (pp. 32–34), and other aspects of "the broader social, political and economic context" (p. 36).

Carrier's article poses clearly the sort of questions anthropologists have felt constrained to ask about using a term like 'friendship' in settings that contrast fundamentally with the contemporary West. His piece is challenging because it pushes hard at a certain take on Silver's line, not only to suggest that the anthropologist is always involved in a double hermeneutic, so that interpretation of the practices and concepts of ethnographic subjects always presuppose an analysis of the practices and concepts of the ethnographic observer's culture, but also (polemically) that this sets up a boundary that separates 'us and them' with respect to friendship, but which cuts across the dividual/individual divide many have accepted as distinguishing Melanesian and Western cultures.

Desai and Killick (2010) find they have reason to critique Carrier's position. Indeed, they appeal to the 'pre-industrial' Aristotle in urging that 'the autonomous self' is not exclusively a product of the capitalist West, but can be produced by other histories (2010: p. 10). For example, the indigenous Mapuche category of the person, as described in the volume by Course, involves an "autonomous individual self, together with the capacity to make friends"; and while sentiment and its revelation is not as central to Mapuche friendship as it is to contemporary Western conceptions of paradigmatic friendship, it does entail the 'ontological' individual (2010: pp. 9, 10). Killick's research with the Asheninka of the Peruvian Amazon likewise underlines "the importance of self-sufficiency and of personal independence and autonomy" in the formation of crucial social relationships (2009: p. 705).

Although key terms in these characterizations evoke ancient controversies in Western philosophy and the foundations of the social sciences, Desai and Killick's aim is to moderate the sort of point made by Paine, Silver, and Carrier, rather than to oppose it entirely. They, and others in their volume, argue that it is important to oppose the tendency of 'new kinship studies' to annex friendship, yet to conceptualize it flexibly enough to explore contemporary transformations of local fields of sociality (Desai and Killick, 2010). For them, patron–client relations no less than those between childhood playmates can count as forms of friendship; they cite and endorse Firth (1999: xiv) on the significant cross-cultural variability in the 'intensity' of friendship. They do not repudiate constructionist notions of personhood but worry that without attention to the specificities of friendship's forms we will miss how these articulate with ideas about kinship and other key relationships, as well as with ideas about 'being a person' (2010: p. 15). They are concerned that if the category of kinship is to engulf that of friendship, we will lose the capacity to track and explain empirical variation in the forms of each and in the relations between them. So while they seek to make connections between different kinds of social relations, they see it as important to retain the distinctions that are present in the empirical material.

Coleman's appreciative afterword to Desai and Killick's volume endorses this line, but adds that being 'residual' can give friendship 'its own power' and (in an allusion to Giddens on modernity's concern with 'pure relationships') render it "deeply and satisfyingly impure" (2010: p. 205). We need, he goes on, to understand that there is "voluntarism as well as constraint in the formation of relationships" (2010: p. 205) a point made by many contributors to the earlier volume (Bell and Coleman, 1999). Much will depend upon the extent to which we can avoid approaching 'voluntarism' and 'constraint' as though they were independent variables in the generation of social outcomes, which would precisely return us to mid-twentieth-century social theory. The continued appeal to the distinction between the ascribed (kin relations) and the achieved (relations between friends) also suggests that such theory remains influential.

Killick observes that "while various attempts have been made to stabilize the category of friendship using ideas of autonomy, sentiment, lack of ritual, and lack of instrumentality, … a general consensus is still lacking." Whether we should therefore "side-step the search for a final definition and instead … base analysis on the indigenous forms encountered" (2009: p. 702) is not entirely clear, for without a specification of the open category 'indigenous forms' Killick's plea might be thought to beg the question. Perhaps, as Aguilar (1999) seems to claim, a commitment to the view that "friendship as any other social phenomenon is culturally constructed … [and] its

manifestations are influenced by localized ways of being human and of being social" (pp. 170–171) will give as much basis for an answer as we need, for it directs our attention to the local context and the concepts and relations that constitute it. In this way, studies of friendship will remain part of the broader dialogues on personhood and ontology that have become topical (especially in the South American and Melanesian literature). However, both Killick (in the works discussed) and Coleman (2010) seem to remain equivocal about constructionist accounts of friendship (and kinship). This is not surprising: what makes a vernacular construction of a relationship one that we are justified in saying is a construction of *friendship*, as opposed to some contrasting species of relationship, does not seem to be a straightforward empirical issue.

As noted earlier, anthropology always faces questions of translation and commensurability. Certainly, what Aristotle wrote about *philia*, which most of his translators render as 'friendship' (its inclusion of primary kin relations notwithstanding), does not make Aristotle party to our interest in whether "different configurations of the relationship between history, personhood, sentiment, and friendship [show] that comparable, if not identical, ideas of friendship may occur in nonwestern cultures" (Killick, 2009: p. 702). And for those interested in friendship in cross-cultural comparison, the question whether the self or 'the autonomous individual,' is constructed, more or less, by this or that social formation, is anything but straightforward. How, relative to a given set of issues and questions, the theoretical picture is most fruitfully put together remains a substantive question not least because it is all too easy for the conceptual bump in the carpet simply to move as we put pressure now on this notion (achievement), now on that (voluntariness), or on another (privacy).

Interestingly, the 'Western view' of friendship that Carrier proposes (which is conjunctive, – "spontaneous and unconstrained" – and features at least one gradable conjunct) must underdetermine the question that Silver's work shows to have been salient in strands of Western history, and which also thematised Aristotle's writings on the subject: how much constraint (by circumstantial need or desire) on the part of those so related is compatible with friendship? That this question is a refraction of the practical, epistemic difficulty that besets agents dealing with trust, goodwill, and mutuality in the course of life, as many ethnographic studies have reported, and which was stressed by Pitt-Rivers, seems to underline a constitutive dimension of friendship.

If this line is correct, it suggests that the anthropology of friendship connects directly to issues that go back to the founders of the social sciences. It is not just that thinking about friendship and values brings out the antinomies involved in the distinction between the jural and non-jural (and its cognates), which was so important to anthropological efforts to find the functional equivalent of Roman Law in small-scale polities (Roman Law was, via Radcliffe-Brown, the source of the concept of the jural that Fortes set in the foundations of his account of kinship's role in the social order (1969: p. 90)), something thought of as a *sine qua non* of social order itself. Rather, the vision of the individual social being that classical theoretical formulations presuppose, and which the problem of order was thought to require for its solution, makes the non-substitutability of the friend or beloved something incomprehensible.

After characterizing the obligatory and external source of "my duties as a brother, a husband or a citizen" Durkheim (1982) grounds sociology in the significance of "types of behavior and thinking external to the individual, but [which] are endowed with a compelling and coercive power by virtue of which, whether he wishes it or not, they impose themselves upon him" (pp. 50, 52). This line hardened later:

> Human beings as individuals are objects of study for physiologists and psychologists. The human being as a person is a complex of social relationships. He is a citizen of England, a husband and a father, a brick-layer, a member of a particular Methodist congregation, a voter in a certain constituency, a member of his trade union, an adherent of the Labour Party, and so on. Note that each of these descriptions refers to a social relationship, or to a place in a social structure. Note also that a social personality is something that changes during the course of the life of the person. As a person, the human being is the object of study for the social anthropologist."
>
> (Radcliffe-Brown, 1952: p. 194)

In Radcliffe-Brown's formulation, becoming friends, (like getting married or divorced), are aspects of the projects of 'individuals' – human beings, in "actually existing social relations" with one another (1952: p. 192) – not of the 'persons' that the social anthropologist is concerned to theorize over, which are complex relations the individual is compelled to enter into that are defined by norms and organized into institutions.

It is not coincidental that the professions and other institutionally defined aspects of Western modernity loom so large in these attempts to define 'place in a social structure.' (In passing, we might note that Durkheim, unlike some of his intellectual descendants, avoided equating what it is for someone to *be*, for example, a brother, and what it is to *act* in accordance with whatever behavioral norms apply to brothers.) In the more highly articulated forms of structural-functionalism developed by Talcott Parsons, the forms peculiar to the twentieth-century nation-state were even more conspicuous in accounts of social structure. There too the friction evident in Fortes' (1969) efforts to differentiate between familial morality and the "kinship rules and concepts" that determine "citizenship in the political community" (p. 87) is generated again.

Without laboring the point with some of the more exotic solutions to the empirically unavoidable problem of 'role conflicts' that this perspective projects upon folks, we note that the difficulties of this sort of approach became clear; but that did not prevent their recurrence in alternative theoretical visions. Today, there is more diversity within the social theory than at any point in its history. Yet, the problem posed by the anthropology of friendship remains: the separation of the motivational bases of interaction and the behavioral evidence available to an observer, in the context of empiricist assumptions that the latter suffices for the specification of action and social norms. The diremption of the intentionality of agency and the behavior of bodies (common to psychological behaviorism and classical social theory and derived from positivistic pictures of science) has proved fateful for social science as a whole, not just in respect of friendship.

The conceptions of social facticity that attracted twentieth-century social scientists is routinely seen as grounded in Hobbesian visions of humans as psychological egoists; Spencer

and Comte (the latter coined the word 'altruism') drew on this vision in forging a sociology that understands human social life to be predicated on the triumph of altruism over our inherent egoism; Durkheim retained a perspective in which the 'dualism of human nature' is basic. Just what that dualism entails, and what significance it has for social theory, is still a fundamental issue for several disciplines, but there is no doubt that Durkheim, at different periods, and with different degrees of clarity, presented the human individual sometimes as that which socialization *controls*, and sometimes as that which socialization *produces*, through a postpartum process that is no less crucial to the product itself than genetic mechanisms and prepartum epigenesis. On the first view, social embeddedness constrains or molds, and, on the second, it is a crucial part of what constitutes, a human person/ego: on the first view the ego is, so to speak, motivationally stratified (and sometimes conflicted), while on the second, the ego is merely motivationally variegated (and sometimes conflicted). There are different possibilities, of course, within this division: for example, on the first perspective there is room for deep differences on the nature of that upon which socialization has its effects, from the ontotheological 'bearer of freedom' to the product of Pleistocene selection pressures. That these visions were differentially taken up subsequently and that they have different implications for the constitution of the 'domains' or 'realms' of social life, is obvious. They also tend to be more or less congenial to those who entertain the thought that social science is relevant to cultural critique and hope that an improvement in future prospects is possible. Finally, these visions have somewhat different implications for ways of thinking about the relationship between friendship and kinship as analytical foci for anthropology.

The point of making these remarks is not simply to bring this piece to closure through a gesture toward its beginnings. We have already cited Coleman's summary views – so evocative of Parsons – about the combination of 'voluntarism' and 'constraint' at work in the formation of social relationships. There is also some contemporary interest in notions like 'doing' family or friendship, 'performing' relatedness or kinship, and 'kinning' as a social practice. Consideration of the anthropology of friendship and its struggles suggests that such formulations preempt long-standing puzzles, or presuppose, without stating, contestable answers to some of the fundamental questions, and reminds us of the possibility – indeed, the standing possibility – of the presence of the theoretical past in the present.

Friendship During Adolescence and Cultural Variations

Hildegunn Fandrem, University of Stavanger, Stavanger, Norway

© 2015 Elsevier Ltd. All rights reserved.

Abstract

First, in this article previous research on the issue of friendship during adolescence is reviewed regarding cultural variations in the understanding of differentiating between individualistic and collectivistic cultures. The main theme is then to raise issues that may question the importance and appropriateness of differentiating cultural variations in these two categories. How the identity consists of different dimensions is focused. Furthermore, the impact of social and cultural changes on peer interaction and friendships is paid attention to. This article concludes with a discussion of future directions for friendship in research on adolescence and cultural variations.

It is argued that theories of friendship have, by and large, been developed with little regard for notions of culture (e.g., Howes, 2009). Rogoff (2003) uses the concept of cultural community to include the aspect of a grouping of people who participate in a shared set of practices and traditions. In this regard, peer group represent a form of cultural community. However, the focus in this article, when it comes to culture, is more cultural variations meaning different national cultures, or characteristics of cultures based on geographic location in the world. The idea of differentiating between individualistic and collectivistic cultures, and research regarding this differentiation related to friendship are presented. The main theme of this article is then to raise issues that may question the importance and appropriateness of differentiating cultural variations in the categories of collectivistic and individualistic cultures.

Generally, friendship formation may be understood by attachment theory (Bowlby, 1969), as the processes of relationship formation embedded in Bowlby's attachment theory are applicable for formation of friendship relationship (Howes, 1996). According to this interpretation, relationships develop through multiple and repeatedly interactive experiences. These experiences, and furthermore, making and keeping friends requires social and emotional regulation skills and social cognition. Thus, theories of social and emotional socialization may also be relevant to the understanding of friendships. Howes (2009) has argued that to form friendships, individuals must recognize the potential friend as a social actor and be aware of the reciprocal nature of social behaviors in social interaction. Harris (1995) claims that cultural norms, either adopted from existing cultural systems or created by children themselves, serve as a basis for children's peer interactions and mutual socialization. Similarly, sociocultural theory (e.g., Cole, 1996; Vygotsky, 1978) emphasizes that culture influence human activities. Thus, the individual internalizes external signs, along with their cultural meanings, during collaborative or guided learning.

While friendships during early childhood may be said to make an important contribution to the development of social cognitive – and social skills beyond experiences with adults (Dunn and Hughes, 2001), friendships during years of youth is however, characterized, or influenced, by also the notion of who one is, or want to be, ones identity. A person's identity is partly influenced by the person's cultural belonging, or maybe also whether the person have several cultural belongings. Perspectives regarding formation of identity are the first issue to be discussed in this article regarding questioning the idea of differentiating between individualistic and collectivistic cultures. Then how the motive for establishing friendships may vary between different groups is focused. Cultural variations will especially in this discussion include the focus on immigrant adolescents, as representatives for multiple cultures. Special attention is paid to aggression as a strategy to gain friendships. The issues will be discussed with regard to recent research. Conditions for social networks and friendship establishment are then discussed, with ethnicity as one of several important factors. Last, the impact of social and cultural changes on peer interaction and friendships is paid attention to. Thus, the discussion of whether differentiating in individualistic vs collectivistic cultures is appropriate is related also to the aspect of modernizing of societies all over the world.

Adolescents Friendships in Individualistic vs Collectivistic-Oriented Cultures

The Role of Adolescence and Peer Experience across Cultures

The most classic and fundamental question in cross-cultural adolescent research is whether all cultures in the world view adolescence as a unique life period. Even if time and duration of adolescence may differ between countries, all societies might be said to have the notion of adolescence. All over the world the time of adolescence is normally relatively brief, about 2 years for girls and 2–4 years for boys (Berry et al., 2002). Exactly how long the adolescent period lasts is, however, dependent of the cultures' demands according to what training is needed for adult roles. For instance, in India children have to fulfill adult tasks from an early age, thus not as much time and attention can be spent on adolescent activities as in the Western world (Saraswathi, 1999). As a consequence, friendship formation in adolescence may play a secondary role in countries like India. Peer interaction is, however, a fundamental part of human development in most societies. Even in India, or other cultures where children are required to spend much of their time helping with family duties, such as caring for their

younger siblings, children and adolescents often do this in company of peers (Tietjen, 2006).

Although research on peer relationships and adolescents friendships has traditionally been conducted in Western, particularly North American, cultures, there has been increased interest in peer relationships in different national cultures in the past two decades. Most of these studies consistently support the view that individual's peer experiences are likely to be affected by cultural norms and values (Chen et al., 2009).

Conditions for Friendship Formation in Individualistic vs Collectivistic Cultures

More specifically, different cultures may place different values on, e.g., social initiative and norm-based behavioral control in adolescents. In Western cultures, which is often characterized as self-oriented or individualistic cultures (e.g., Hofstede, 2001) acquiring autonomy and assertive skills is an important socialization goal, and also social initiative is viewed as a major index of social maturity. In addition, self-regulation and control are encouraged. The cultural emphasis on individual decision making, however, allows individuals to maintain a balance between the needs of the self and those of others. Thus, behavior control is often regarded as less important, especially if it is in conflict with the attainment of individual goals (Triandis, 1995). On the contrary, in non-Western cultures that are characterized as more collective or group-oriented societies, social initiative may not be highly valued because it may not facilitate harmony and cohesiveness in the group. In these cultures to maintain group harmony is encourage, thus, individuals need to restrain personal desires in an effort to address the needs and interest of others. Self-control may be emphasized in a more consistent and absolute manner, and the lack of control may be regarded as a serious problem during childhood and adolescence (Triandis, 1995).

How active and prosocial–cooperative behavior vs shyness is valued and perceived is also found to differ between individualistic and collectivistic cultures. Peers and adults in Western cultures regard children and adolescents who are active and assertive in their peer interactions as socially competent (e.g., Rubin et al., 2002). Thus, sociability is valued and may be seen as an important aspect to be accepted by peers and to achieve success in friendship formation. Opposite, adolescents who display shy and wary behaviors are often viewed as socially incompetent and immature. Research shows that shy-inhibited students are likely to experience low peer acceptance and poor social adjustment in Western cultures (e.g., Coplan et al., 2004). Especially shy-inhibited boys in North America have been found to experience difficulties in peer relationships (e.g., Caspi et al., 1988). Result from another study showed that when shy-inhibited children in Canada made passive and low-power social interactions, they were more likely than others to receive fewer positive responses and more rejection from peers (Chen et al., 2006), while shy-inhibited Chinese children who displayed the same behavior (made passive and low-power interactions) were, on the other hand, more likely to receive positive responses and being accepted by peers (Chen et al., 1995). Thus, shyness-inhibition is not necessarily perceived as social incompetence or associated with social adjustment problems in collectivistic-oriented cultures, where social initiative and assertiveness are less valued. As Indonesian children and adolescents are found to more often display shyness-inhibition compared to Americans (Farver and Howes, 1988), how behavior is perceived, or to which degree it is valued, may also influence the prevalence of the actual behavior.

When it comes to prosocial–cooperative behavior individual in Western societies attempt to maintain a balance between prosocial concerns and individual freedom of choice. Thus, interpersonal cooperation and prosocial behavior, and thus friendship establishments, are seen as a personal decision based on factors such as how much one like the target person (Greenfield et al., 2006). In collectivistic-oriented cultures, responsiveness to the need of others may, on the other hand, be seen as a fundamental commitment (Miller, 1994). Thus, there might be a considerable pressure on children in these cultures to view prosocial cooperativeness as obligatory.

Researchers have, however, found little cultural variations in the linkage between prosocial–cooperative behavior and the quality of friendships, this suggests that social behavior based on the consideration of the interests of others or the group may be a universal antecedent of peer acceptance, and thus a universal factor for friendship establishment. This suggests that aspects of culture in friendship formation might be overestimated.

In most cultures, children and adolescents usually have reciprocal friends (e.g., French et al., 2003; Schneider et al., 1997). One may, however, argue that there might be cultural variations in the extent to which group integration or development of friendships is encouraged (e.g., Sharabany and Wiseman, 1993). As involvement in peer relationships increases from childhood to adolescents in North America, because of the desire of youth to become autonomous from the family (Rothbaum et al., 2000), more collectivistic-oriented cultures emphasize conformity to others and commitment to social relationships. In group-oriented cultures, children and adolescents are expected and encourage to maintain strong social affiliations and to identify with the group (Sharabany, 2006). Thus, involvement with age mates and friendship formation typically occurs within extended family networks of siblings and cousins, leaving little opportunity for relationships with nonkin. There may also be less dyadic friendships in group-oriented cultures (Sharabany and Wiseman, 1993). However, schools may be an arena that, independent of cultural orientation, bring together large numbers of nonkin, same-age adolescents, thus providing opportunities to form friendships also across family bonds.

The Role of Friendship in Individualistic vs Collectivistic Cultures

Friendship intimacy is associated with constructs as sensitivity, mutual understanding, exclusivity, attachment, emotional closeness, and trust, and may therefore be difficult to understand across cultures (Chen et al., 2009). Chen and French (2008) argue, however, that the extent to which these different aspects are emphasized may vary across cultures. Although it is claimed that friendship in collectivistic-oriented cultures seem to be more intimate than those in

individualistic-oriented cultures (Triandis et al., 1988), Sharabany (2006) suggests, based on his research among Arab and Jewish children in Israeli Kibbutz, that in some collectivistic societies, friendships are characterized as low in intimacy because of the availability of other sources of emotional support. This is also supported by the studies of French et al. (2005, 2006a) finding Indonesian to report lower intimacy than their North American counterparts. Indonesian students have also been found to be less likely to develop close friendships, because they are encouraged to focus on integration into general peer networks and larger community (Jay, 1969). However, friendships among South Korean adolescents have, e.g., been found to be highly intimate (French et al., 2006a,b). In addition, Schneider's research shows that more close and harmonious friendships are reported among Italian (Central and Southern), than among Canadians. Also, within the United States, e.g., Latino adolescents perceive their friendships as more intimate and closer than adolescents in European American and other individualistic-oriented groups (Gonzales et al., 2004; Way, 2006).

While in Western cultures the support of friends may be an important mechanism to accomplish the socialization goal of developing confidence and positive views about the self (Sullivan, 1953), Chen and French (2008) argue that the role of friendship in promoting self-worth may be less salient in many non-Western cultures, where the development of self is not considered an important developmental task. This is supported by research on Chinese (Chen et al. 2004), Indonesian (French et al., 2005), and Arab and Caribbean (Dayan et al., 2001) children, as none in these studies reported the enhancement of self-worth as an important function of friendship. Instead of self-validation, research shows that instrumental aid and assistance, like e.g., sharing money, protection from harm, helping others solve problems and learn social skills appears to be important aspects for friendship in Asian nations, such as China (Chen et al., 2004), Indonesia (French et al., 2005), South Korea (French et al., 2006a), the Philippines (Hollsteiner, 1979), and in Latinos societies, such as Cuba (Gonzales et al., 2004) and Costa Rica (DeRosier and Kupersmidt, 1991) and also in low-income black and Hispanic adolescents in America (Way, 2006).

Research in North America shows that as interaction within small groups decline from middle childhood to adolescence, affiliation with multiple groups and larger crowds becomes more salient during adolescence (e.g., Brown, 1990). The various peer groups than can be identified; e.g., 'jocks' 'brains,' 'nerds' etc. may be said to reflect individualistic values as they are more individual characteristics than they focus on relations (Hofstede, 2001). Thus, adolescents in Western cultures may be said to form mainly peer groups on their particular individual interest. As adolescents increasingly seek independence and attempt to avoid group restrictions, there is furthermore a general loosening of group ties, consequently, adolescent's sense of belongingness decline steadily with age (e.g., Rubin et al., 2006). In general, the role of peer groups in adolescents is often highlighted as a major social resource for fulfilling individual psychological needs such as formation of self-identity and the development of positive self-perception and self-feelings (Chen et al., 2009). In collectivistic-oriented cultures, the balance between the pursuit of independence and personal identity, and the commitment to group undertaking tend to be less evident compared to individualistic-oriented cultures. Research shows that adolescents from e.g., China usually describe group activities in terms of how they are in accordance to adult's social requirements and standards, such as maintaining interpersonal cooperation and collectivistic well-being (Chen et al., 2004). Thus, we may conclude that the culture may pay particular attention to the nature of peer groups and friendships, in terms of whether social relationships or group activities are guided by the 'right' social goals.

The Role of Culture in Formation of Identity in Adolescence

All over the world identity formation may be defined as a lifelong process characterized by cycles of exploration and consolidation, as well as experiences of competence and vulnerability (Grotevant and Cooper, 1998). Although the process is lifelong, it takes new dimensions during years of youth because of the confluence of physical, cognitive, and relational changes during this period. Thus, there are reasons to believe that adolescence, especially early adolescence, may be a turbulent period (Chen and Ferruggia, 2002). However, the time of adolescence is not necessarily a period of 'storm and stress,' as claimed by Western developmental and clinical psychologists throughout most of the twentieth century (Hall, 1904). Berry et al. (2002) claims that the time of adolescence is most of all a time for learning new social roles, with attendant psychological tensions. However, deciding who one wants to be may not necessarily be an easy task, and difficulties in identity development have been associated with serious problematic behavior, as e.g., substance abuse (Jones et al., 1989). Generally, adolescence may be said to be the most difficult time of life. This claim is supported by research, which generally finds depression to be rare among children (Kessler et al., 2001) while among adolescents depressive mood is found to be higher than among their parents (Kandel and Davies, 1982).

Descriptively, a range of aspects is traditionally held to concern identity, independent of where one is from. Dimensions like nationality, ethnicity, gender, social memberships and group characteristics, individual character, personality, and social preferences are all part of the identity (Verkuyten, 2005). Hence, identity consists of both collectivistic (e.g., ethnic) and personal (e.g., individual characteristics) dimensions. *Ethnic identity* may be said to refer to the idea of common origin (Kanstad, 1994) as it comprises identification with one's ethnic group or culture of origin. This dimension is, furthermore, an example of a stable dimension. The *national identity*, on the other hand, refers to the country or nation, in which one lives. Hence, it comprises identification with the larger society surrounding the person and thus it changes with resettlements. The concept of *cultural identity* covers both the ethnic and national dimensions. Triandis et al. (1990) define culture as those constructs shared by speakers of a particular dialect, living in a proximal location, during the same historical period. Thus, culture may not necessarily refer to only a country. Important in this sense is, however, that cultural identity refers to more than the group category that one chooses, it involves a sense of belonging to one or more cultural groups and the

feelings associated with a group membership (Phinney, 1990). If culture refers to countries it is important to have in mind, regarding adolescents that have migrated, that national and ethnic identity differ for the same individual. Furthermore, the relationship between the two dimensions needs to be in focus as it might have an influence on psychological and sociocultural adaptation, and the possibility for friendship formation for this group of adolescents. *Social identity* may also be said to occur when one discover that one have something in common to someone, at the same time as one discover that there are people one have little in common with. This type of collectivistic identity comprises the notion of a social group (e.g., gender, status, age). Thus it is also less stable. Friendships play an important role in the formation of especially social identity. At the end all the collectivistic dimensions of the identity (ethnic, national cultural, and social) are given a personal expression through the *personal identity*. The personal dimension of the identity is established on the basis of each individual's personal experiences. Thus, personal identity is never the same among different individuals. It is also claimed that because of increased *global* and *social* mobility the personal, or subjective, aspect of the identity becomes more and more important (Fandrem, 1996).

From this we may claim that identity is constructed and maintained through social interactions, it changes over time and context, and across generations. It is, however, through the time of adolescents that the formation of the identity is an especially critical developmental task (Marcia, 2002; Phinney et al., 2006). How the identity process develops is highly dependent on the peers, the family, the community, and the context to which the adolescent is exposed. As mentioned earlier, independent of culture, parents (vertical relations) are the most significant others to the individual in the earliest years of life. With increasing age, especially during years of youth, peers (horizontal relationships), however, become increasingly significant. Research have shown that during years of youth, peers become more important to the individual, and the amount of time spent with family members decreases (Laible et al., 2000; Larson et al., 1996).

Considering that cultural variation in this article also includes variations regarding individuals belonging to more than one culture, immigrant adolescents should be left a comment. In immigrant families, especially the mother is the one who represents the culture of origin. In addition to generally being more interested in keeping traditions, mothers often spend more time with people from the same origin as themselves, especially if they are not employed and thus through work gain social relationships with people from the dominant culture. Adolescents, on the other side, gain social relationships with peers from the dominant culture at school. Thus, for immigrant adolescents, parents and peers may represent more distinct values, compared to what is the case for native adolescents. Consequently, immigrant adolescents may struggle more than natives during development of their identity. For adolescents in immigrant families, formation of ethnic identity involves examining also the ethnic attitude, values, and practices learned at home from their immigrant parents and considering them in relation to those of their peers (Phinney, 1989).

Regarding the different dimensions of the identity, for adolescents with immigrant background also the concept of *ethnic minority identity* (Phinney, 1990) may be used, besides *majority identity* or *host national identity*, which refers to the individual's identification with the majority or host society. It has been suggested that it is possible to have high or low identification on both constructs, or a high identification on one construct, and a low one on the other (Phinney, 1990; Sanchez and Fernandez, 1993). Furthermore, a strong sense of ethnic identity devoid of positive identification with the larger society may aggravate psychological conflicts; this may in turn influence the opportunity to establish friendships for this group.

The Role of Aggression in Gaining Friendships

Western cultures, where competitiveness and the pursuit of personal goals are in focus, seem to allow, or also encourage, aggressive behavior to some degree. Despite the general discouragement of this kind of behavior, research shows that aggressive adolescents may receive social support from peers, and are sometimes even perceived as 'stars' in their peer groups (Cairns and Cairns, 1994). Opposite, non-Western cultures, where group harmony and personal control are important, tend to inhibit aggressive behavior (e.g., Bergeron and Schneider, 2005). This may influence the prevalence of aggressive behavior in different cultures.

There may be cultural variations also in the expectations of how behavior is to be performed. For example, bullying is an externalizing behavior problem, in which there are three key elements: (1) it is a type of aggressive behavior; carried out toward a victim, (2) it is repeated over time, and (3) there is an imbalance of power in favor of the perpetrator(s) when the bullying occurs (e.g., Olweus and Roland, 1983; Smith et al., 2002). Although this definition is widely accepted across different cultures, bullying may be conceptualized slightly different according to language and culture (Smith et al., 2002). In, e.g., Japan the concept of bullying, which is 'ijime,' includes an aggressive behavior, which is performed together with somebody. The collectivistic dimension (Hofstede, 2001) is automatically included in the use of this concept. Bullying may appear in different ways, for instance, by teasing or direct verbal aggression (such as name calling), active exclusion from a social group, also called indirect aggression, and/or by physical assaults or direct physical aggression (e.g., Björkqvist et al., 1992; Roland, 1998). These different forms are however identified across different cultures.

Prevalence rates of bullying vary according to methods used and samples investigated, and as mentioned this may vary in different countries as, e.g., different concepts are used. A systematic comparison of bullying among girls and boys between different countries is done in a study of Craig and Harel (2004). For the 35 other countries in this study the percentage was ranging between 2.3% (Sweden) and 29.5% (Lithuania) for girls and 5.1% (Sweden) and 49.8% (Lithuania) for boys. Generally, independent of which country the bullying is taking place, the figures of being victimized decrease with increasing age through primary and secondary school, while the figures for bullying others seem to be more stable, or there is a small increase, during the same period (Craig and

Harel, 2004). In addition, gender differences do not seem to differ between countries. Bullying is found to be more frequent among boys compared to girls, the gender difference is however smaller concerning victimization (Craig and Harel, 2004; Olweus, 1978).

Regarding characteristics of bullies and victims, there is solid evidence for concluding that victims as a group are different from other individuals not victimized (Hawker and Boulton, 2000; Isaacs et al., 2001). Focusing on bullies, most researchers now consider aggressiveness as a strong predictor for bullying others (e.g., Berkowitz, 1993; Dodge, 1991; Olweus, 1978; Olweus and Roland, 1983; Roland, 2002). Aggressiveness may be defined as the trait, or tendency, to wanting to hurt or attack someone. In the research literature, *reactive* and *proactive* aggressiveness are the concepts often used for the two different main types of aggressiveness (e.g., Card and Little, 2006; Dodge, 1991; Vitaro et al., 2006). While *reactive* aggressiveness is theoretically grounded in the frustration-aggression model and the behavior occurs as an angry reaction to a perceived frustration (Berkowitz, 1989), *proactive* aggressiveness has its roots in social cognitive theory and is related to a planned behavior controlled by external rewards and reinforcement (Bandura, 1986; Vitaro et al., 2006). Thus, there are different drives in the two different types of aggressiveness; while anger is the central emotion in reactive aggressiveness, pleasure through social rewards is the dominant emotion in proactive aggressiveness. Only a few studies have empirically investigated reactive and proactive aggressiveness among bullies and nonbullies (e.g., Salmivalli and Nieminen, 2002). Roland and Idsøe (2001) distinguished between power-related proactive aggressiveness and affiliation-related proactive aggressiveness while investigating the associations between different types of aggressiveness and bullying behavior. In power-related proactive aggressiveness, it is a goal for the individual to act aggressively to feel power over the victim. In affiliation-related proactive aggressiveness, the goal is on the other hand to gain affiliation with another individual with whom he or she bullies others. Thus, affiliation-related proactive aggressiveness might to some degree be related to the drive of establishing friendships. In the study of Roland and Idsøe (2001), power-related proactive aggressiveness was found to be associated with bullying behavior among boys in eighth grade. While for girls in grade eight the results indicated higher associations between bullying others and affiliation-related proactive aggressiveness. Thus, adolescent girls seem to use bullying as a strategy to gain friendships more than boys.

In the last years, the focus on bullying as a group phenomenon has increased. Affiliation and peer acceptance as underlying motives of aggressive behavior make it relevant to focus on peer groups when studying aggressive behavior and bullying. When viewing bullying as a group phenomenon, the bullying behavior is determined not only by characteristics of bullies and victims but also by social relationships or roles within the group (e.g., Salmivalli et al., 1996). Many of the studies on bullying and peer groups focus on social status and view bullying as an attempt to gain social status and friends, or to be accepted, by peers (e.g., Olthof and Goossens, 2008; Salmivalli and Peets, 2008; Veenstra et al., 2007). However, studies applying these ideas to better understand peer relations across different cultures are still relatively scarce. Those found emphasize, however, the affiliation motive to be strongly related to bullying for immigrant boys, but not to the same degree for native boys (Fandrem et al., 2010; Fandrem et al., 2009; Strohmeier et al., 2012a,b). Thus, even if research that investigates level differences between natives and immigrants in different countries are not conclusive (e.g., Boulton, 1995; Eslea and Mukhtar, 2000; Moran et al., 1993; Strohmeier and Spiel, 2003), there seem to be consistence across cultures regarding motives for bullying. Furthermore, when immigrants and natives in, e.g., Austria and Norway are compared the studies show similar results (Strohmeier et al., 2012a). Thus, despite different cultures, e.g., different migration history, different national policy for migration and immigrants, differences in the composition of the immigrant groups in the country, there are some psychological mechanisms across different nations that are the same when it comes to need for friendships and strategies for achieving friendships. Independent of which culture one originates from, or live in, it seems like being multicultural increase the chance for using aggression as a strategy to gain friendships. Thus, it is not the *kind of culture* that necessary matters, but *being in the situation of feeling loss of cultural belonging* may influence how friendships are established.

Other Contextual Conditions for Social Networks and Friendship Establishment

As mentioned, time spent with peers increase during years of youth, usually on the expense of time spent with family members (Larson et al., 1996). Furthermore, as peer attachment is found to be relatively more influential on adolescent adjustment than parent attachment (e.g., Laible et al., 2000), peers play the most crucial role in adolescent's social networks. A social network may be defined as a set of connections between a limited set of persons, and in addition, characteristics of the connections can be used to understand the social behavior of each person (Mitchell, 1969). Networks are also formed and sustained by the cohesion or attachment, which is to be found between the persons in the network (Bøe, 1993). From this, we may also conclude that affiliation seems to be a central mechanism in a peer network.

In all cultures, all over the world, most adolescents affiliate with a peer group. In the first years of youth peer groups often comprise same-sex members, with more mixed-sex groups appearing in late adolescence. In both individualistic and collectivistic-oriented cultures more girls than boys form mutual friendships, and generally girl's friendships tend to be more stable over time (e.g., Beneson et al., 1997; Schneider et al., 1997). The size of peer groups seems to increase with age. Boys' groups tend to be larger than girls' groups. Research in many countries, including the United States, China, Japan, Singapore, and Senegal, suggest, furthermore, that boys more often than girls belong to groups and are more susceptible to peer pressure than girls (e.g., Beneson et al., 1997; Dekovic et al., 2002; D'Hondt and Vandewiele, 1980; Salmivalli et al., 1997; Sim and Koh,

2003). However, in some other studies in the United States and China, differences between boys and girls are not reported (Cairns et al., 1995; Chen et al., 2003).

Adolescents form several smaller networks or subgroups, inside a class at school or on different leisure arenas. Within these smaller peer networks group mechanisms connected with aggressive behavior might be even more powerful than at the class level, because social influence can be especially effective within small friendships groups (Salmivalli et al., 1997). Research shows that both ethnicity and aggressive behavior make young people affiliate with one another (Cairns et al., 1988; Espelage et al., 2003; Farmer et al. 2003; Glueck and Glueck, 1950; McPherson et al., 2001; Salmivalli et al., 1997). More specifically, e.g., the study of Salmivalli et al. (1997) found that Finnish students who behaved in similar or complementary roles in bullying situations (bullies, assistants/reinforces, defenders, victims, and outsiders) established networks with each other. Also, among Chinese children homogeneity has been found regarding leadership status, aggression, and learning problems (Chen et al., 2003). Thus, peer groups are likely to be homogenous on social and behavioral attributes across different cultures. But, homogeneity is not necessarily the rule; inequality according to both ethnicity and aggressiveness are found, especially proactive aggressive adolescents, and nonaggressive adolescents are found to interact with each other (Estell et al., 2007; McPherson et al., 2001).

Regarding immigrant adolescents, social contact with peers from the national vs ethnic group is a central factor in the acculturation process, i.e., the process of psychological and sociocultural adaptation one face when moving to another culture (e.g., Berry, 1997). Social interactions, or friendships, are widely used in assessing acculturation (e.g., Berry et al., 2006). An immigrant may be involved with members from the larger, or host, society, or with others from ones own ethnic group. Time is one aspect that may influence degree of contact with members from the larger society vs culture of origin. Immigrants usually extend their contact with the host society over time. Titzmann et al. (2012) found that using the new host language more often appeared to be a crucial variable for lower levels of *friendship homophily* (i.e., the preference for intraethnic over interethnic friends). However, ethnic ties typically remain strong. Several studies suggest the case of in-group preferences; i.e., contact with peers of ones own ethnic group (Hallinan and Williams, 1989; Hamm, 2000; Schofield and Whitley, 1983), especially regarding pupils in small ethnic minorities (Quillian and Campbell, 2003). Another aspect of importance that has been suggested is that the number of intra- and interethnic relationships reflects the opportunity for establishing these relationships (Baerveldt et al., 2004; Moody, 2001). Consequently, the number of available adolescents of different ethnicities influences ones affiliations, and thus the ethnic composition of peer groups and the possibility to form friendships across ethnicity. The study of Titzmann et al. (2012) that was based on information from Russian Jewish and ethnic German Diaspora migrant adolescents (i.e., migrants returning to the country of their ancestors from the former Soviet Union) in Israel and Germany, respectively, also showed higher levels and a less pronounced decrease of friendship homophily in Israel as compared to Germany. Especially, acculturation-related variables were in this study found to be best at predicting intercept and slope of friendship homophily.

Research on adolescents shows that interaction with peers from one's own ethnic group is strongly related to ethnic identity (Phinney et al., 2001), thus contact with ethnic alike peers seems necessary in order to keep ones ethnic identity. Although there are wide individual variations in immigrants, almost all research on ethnic identity carried out in the United States suggest high scores on ethnic identity in this group. Compared to ethnic identity, there has been far less attention paid to the conceptualizing of national identity and to studying immigrants identification with the host society. Phinney and Devich-Navarro (1997) found adolescents to vary according to if they have a strong positive sense of belonging to the host, or larger, society, or if they feel they are excluded or rejected by the larger society. The school is an important arena, in which adolescents form friendships. Studies in schools including adolescents from many different ethnic groups show that the pupils vary to which extent they relate with people with the same ethnicity as themselves or mix with others (e.g., DuBois and Hirsch, 1990; Semons, 1991).

Focusing specifically on the issue of bullying and friendship, research is in line with the research on peer groups and aggressive behavior generally; bullies tend to be friends with other bullies, but are not segregated from peers who are not bullies (Estell et al., 2007; Pellegrini et al., 1999; Rodkin and Hodges, 2003; Salmivalli et al., 1997). However, few studies have investigated which factors, besides having migration experience, influence whether bullies affiliate with other bullies or with their nonaggressive peers.

In the study of Roland and Idsøe (2001), where a distinction of proactive aggressiveness is made (affiliation-related proactive aggressiveness vs power-related proactive aggressiveness) the findings at least shed some light on this aspect. The results shows that in grade five the bullies (both girls and boys) seem to be motivated by affiliation, and not by power at all. In grade eight the pattern changes, as among these older pupils power is found to be associated with bullying behavior as well as affiliation, though this is applicable only for the boys. Among girls in grade eight affiliation-related proactive aggressiveness is still the only type of proactive aggressiveness that is associated with bullying. Thus, age and gender may be factors that influence if bullies affiliate with other bullies. The above-mentioned results suggest that girls use aggression to gain friendships more than boys do, at least in early adolescence. Regarding gender, another study shows that antisocial girls, more than antisocial boys, find it important to be accepted by boys in general, while for boys it was important to be accepted by boys only if they also where bullies (Olthof and Goossens, 2008). Hence, girls who bully are likely to establish friendships also with nonbullies, especially if these are boys.

Bullying is a way to interact with peers. In affiliation-motivated bullying, there is an interaction not only between the bully and the victim only, but also between bullies that bully together, or the group of bullies. If the bullying is mainly associated with affiliation-related aggressiveness, the bully may carry out the aggressive act on order

to feel affiliation with cobullies. Having a common enemy makes the relation between two parts stronger. From this, we may conclude that bullying might be a strategy to gain friendships.

To be affiliated with peers includes being affiliated with what the peers represent. For example, an immigrant boy this means that it is crucial with whom he bullies regarding what he wants to feel affiliated to. If the immigrant has mainly other immigrants as cobullies, they affiliate with their culture of origin, thus the bullying behavior may be interpreted also as a separation strategy (Fandrem et al., 2010). On the other hand, if immigrants bully with both immigrants and natives, they also interact with people in the host culture, the outcome then could be interpreted as integration. This shows how bullying behavior among immigrants also may be related to acculturation strategies, i.e., how one choose to adapt into a new culture (see Berry, 1997).

The Impact of Social Change in Societies

Besides that migration is characteristic of modern society, today's urbanization of traditional rural societies and modernization generally should also be taken into account. Research has shown that, e.g., industrialization of rural areas has resulted in adolescents having fewer interactions with their extended kin group and a decrease on cooperative and obedient behaviors (e.g., Graves and Graves, 1983). Urban lifestyles may be said to increase affluence and change the values in the culture to, e.g., more individual autonomy, which in turn may influence on the character of friendships. Social relationships tend to serve a more utilitarian function in societies where relying on others for basic needs is essential (Guthrie, 2006). Chen et al. (2009) argue that increased value of personal independence and social initiative during modernization may undermine the utilitarian function of relationships and enhance their role in providing emotional support.

More specifically, in China the traditional utilitarian and instrumental type of friendship is losing significance, as the country moves toward a market economy and stronger legal infrastructure (Tamis-LeMonda et al., 2008). Also, studies in Berlin support this notion (Little et al., 1999): When adolescents in former East Berlin was compared to adolescents in West Berlin, the Eastern adolescents reported less fun and enjoyments within their friendships then the Western, largely due to the adult control of their interactions with friends. However, with the changes of the education system after the German unification, friendships and group activities among children in East Berlin seem to be based more on personal choices and are less controlled by adults, thus friendships in East Berlin today are characterized of more play and intimacy than earlier.

On the basis of these studies we may argue that as the whole world get more modernized, adolescents all over the world increasingly appreciate the function of friendships in fulfilling individual psychological needs. Thus, the differentiation between individualistic and collectivistic-oriented cultures will in the future lose it's meaning.

Conclusions and Future Directions

The research reviewed in this article show inconsistency in findings related to collectivistic and individualistic-oriented cultures. This may make us conclude that the nature and quality of adolescents' friendships may depend on complex social, historical, and ecological factors. Thus, it is not necessarily the culture itself that matters. Generally, there seem to be a need for focus on specific socioecological circumstances and factors. Future research needs to take into account specific social circumstances and other historical and ecological factors, as well as emphasizing individuality. Although one may claim that culture may to some degree affect not only overall social engagement but also the nature or characteristics of peer interaction, learning new social roles also has to do with many individual characteristics, e.g., learning ability. External factors as the family, the school, the neighborhood and peers may play an important role in regulation of behavior, psychological autonomy, and connection with significant others during adolescence (Barber and Olsen, 1997). This emphasize that the focus on *national* culture might be overestimated. Taken into account also all the different dimensions of ones identity, future research should to a higher degree pay attention to that why and how people interact and form friendships is due to a multifaceted and complex set of factors.

Also *global* and *social* mobility of today make the individual aspect of the identity increasingly important (Fandrem, 1996). Thus, there might also be large individual differences within the same country or type of culture, i.e., Western countries. Research shows that, e.g., shyness has been linked with fewer negative outcomes in Swedish youth compared to American youth (Kerr et al., 1996; Caspi et al., 1988). This aspect, in addition to how the undergoing dramatic reforms toward a market economy in China have made, e.g., the adaptive value of shyness-inhibition decline in urban children (Chen et al., 2005) emphasizes the need to question whether the differentiation between Western and non-Western cultures should be paid as much attention as it has until recently.

This article has showed us that cultural norms and values may affect the display of significance of adolescent's social behaviors in peer interaction and friendships, and also the structural and functional features of friendships and organization of peer groups. Based on the inconsistency of research results there is, however, a need to emphasize that macrolevel, social (e.g., class, religion, etc.), economic and individual factors also need to be taken into account when studying adolescent relationship and friendships. Thus, within-culture factors should receive greater attention. With the more use of sophisticated methodology, future studies will be able to take into account different levels of social complexity, and thus may reduce the importance that until now has been attributed culture.

In addition, cross-cultural issues in peer relationships and friendships should be examined also from a developmental perspective in future studies. By the use of longitudinal studies antecedents, concomitants, and outcomes, as well as developmental patterns can be identified.

Friendship During Childhood and Cultural Variations

Abstract

Throughout the world, children seek out friendships and friendships develop naturally over time. Despite cultural differences, friendships are founded on several core features that transcend cultural boundaries, including reciprocity, mutual liking, and similarity. Theories of childhood friendship began with the work of Harry Stack Sullivan in the 1950s and have developed more broadly since the 1970s. Childhood friendships are typically evaluated based on prevalence, characteristics, stability, and quality. Friendships are beneficial for children's social and emotional development, and may buffer children against the negative life events.

Friendship during Childhood

Friendship is a type of relationship between two people based on mutual liking, wherein each member affirms the friendship, does not feel obligated to continue the relationship, and is not primarily motivated by instrumental need (Rubin et al., 2008). Distinct from popularity, which is the degree of unilateral acceptance by peers, a key feature of friendship is mutuality. Friendships are 'horizontal' relationships; they are equal in nature.

Although there is emerging evidence on cultural variation in childhood friendship, the vast majority of research focuses on children from Western cultures and the exact nature of cultural differences is poorly understood. Nonetheless, certain features of friendship appear to be universal and therefore less likely to vary by culture. Reciprocal exchange, similarity, and mutual positive regard and liking appear to be definitive features of friendship and are sometimes called deep structures of friendship (Hartup and Stevens, 1997). This article will explore theories and perspectives, characteristics and correlates, and cultural variation and similarity in childhood friendship.

Prevalence and Assessment

Although prevalence rates differ depending on whether or not children are asked to identify a friend or a 'best' friend, between 60 and 80% of children have at least one friend (Rubin et al., 2008). The most common method for assessing childhood friendship is sociometric. Typically, children are asked to nominate a specified number of classmates who they consider 'friends.' Sometimes, children are also asked to rank the closeness of their friends, differentiating between their 'very best' friend, and their second, third, fourth, and so on, best friends. The responses of the children within the classroom are compared, and reciprocal nominations are treated as evidence of friendship.

Theories of Childhood Friendship – Historical Perspectives

Childhood friendship has gained attention in several disciplines, including developmental psychology, sociology, and anthropology. Interest into the social development of children gained popularity during the 1920s and 1930s, yet a particular focus on friendship did not appear until several decades later. In the early 1950s, Harry Stack Sullivan brought the importance of friendship in child development research into focus. Previous literature in child psychology had investigated peer interactions and social development to the exclusion of friendship. Sullivan (1953) interwove social development theory with interpersonal theory and posited that social relationships satisfy interpersonal needs at different developmental stages. He concluded that childhood friendship becomes particularly important during preadolescence when the need for acceptance shifts to the need for interpersonal intimacy. According to Sullivan (1953), one of the primary outcomes of preadolescent friendship is the development of self-worth. Self-worth develops as children learn that the ideas/opinions/values they hold and share with others are important and that another person uniquely values their self-worth.

Continued focus on the importance of childhood friendship is due to the work of Willard W. Hartup and colleagues (e.g., Hartup and Sancilio, 1986), who stressed the importance of research on childhood peer relations and friendship relations. Throughout the 1970s and 1980s, there was a significant increase in research devoted to how children conceptualize friendship, behave with friends, and differ by gender and age. Hartup helped move research focus away from peer interactions toward a deeper understanding of the essence of friendship, by integrating theories of development, cognition, interpersonal relations, and attachment. Emphasizing the developmental nature of friendship over the lifespan, Hartup and Stevens (1997) differentiated between the deep structure and surface structure of friendship. While the deep structure can be thought of as the foundation or essence of friendship, the surface structure implies the observable features of friendship, including the actual interactions, activities, and exchanges between friends. The deep structure tends to be developmentally stable, whereas the surface structure of friendship is more subject to change.

The observable changes in friendship that occur as children mature must be understood in relation to children's cognitive and social development. Drawing from the work of Sullivan, Selman and colleagues (Selman, 1981) introduced a stage theory of friendship that tied closely with Jean Piaget's theories of cognitive development (*see* Piaget's Theory of

Cognitive Development). According to Selman, children move from a superficial level of friendship (e.g., based on physical and geographic factors, such as propinquity) to levels that include the deeper characteristics of friends (e.g., reciprocity, trust, and empathy).

Research confirms many of the theories of Sullivan and Selman. Young children first become friends based on propinquity or proximity (e.g., classroom, homeroom, or neighborhood). Children are more likely to be friends with those who behave as they do or are from similar racial or ethnic backgrounds, otherwise referred to as homophily. However, in a groundbreaking study, Bigelow and La Gaipa (1975) empirically demonstrated developmental changes in children's perceptions of their friendships. Validating the theories of Sullivan and Selman, Bigelow and La Gaipa (1975) found that second and third grade children expect that their friends will provide material goods, have similar demographics, and engage in common activities. As they age, children's perceptions of friendships become less superficial. As their cognitive development matures through 4th–6th grades, children incorporate the dimensions of acceptance, loyalty, commitment, and genuineness when choosing friends. By preadolescence (e.g., 7th grade), children consider intimacy and shared values important to their friendships, and this also marks the transition into adolescence.

Youniss (1980) also expanded on Sullivan's theory by incorporating Piaget. Youniss criticized traditional models of child development for relying on the parent–child relationship as the sole vehicle for children's social and cognitive development. Termed the Sullivan-Piaget thesis, Youniss (1980) called attention to the importance of peer relations and declared that children's relations with other children and adults serve equally important, but distinct, functions in social development. Whereas the parent–child relationship requires the child to learn and accept rules and values from or through the adult, friendships allow children to socially develop with other children in ways that would be impossible to develop alone or with adults (e.g., interpersonal sensitivity, reciprocity, mutual understanding, cooperation, and intimacy). Similarly, Shantz (1983) outlined three developmental features of childhood friendship: (1) a shift from strict behavioral (e.g., activity-based) interactions to emotional relationships, (2) progression from egocentric to mutually beneficial relationships, and (3) evolution from unstable but conflict-free relationships to those that are stable and able to withstand conflict.

Psychosocial Associations of Friendship and the Lack Thereof

Friendship development during childhood is necessary for a child's successful social, cognitive, and emotional development. Children develop core social skills through the experience of companionship, intimacy, and conflict resolution with friends. Such skills may be enhanced by a qualitatively stronger relationship with a best friend. Although the literature is mixed, friendships may also contribute to stronger emotional development by providing a context for learning emotion regulation, emotional intelligence (i.e., understanding the emotions of others), and appropriate emotional expression. Cognitively, friendship enhances the child's development of verbal and nonverbal sharing, problem solving, and advanced communication skills.

The presence and stability of a friendship have social and emotional implications for children. Children who are friendless are more likely to be lonely, as are children who have lower quality friendships. Furthermore, children who have no, few, or low-quality friendships are more likely to develop depression if they experience significant feelings of loneliness. By comparison, children who have stable best friends are more likely to exhibit prosocial behaviors (*see* Prosocial Behavior during Childhood and Cultural Variations), use more effective conflict management strategies, and be more popular with peers. For example, children with stable best friendships are more likely to use effective problem-solving strategies (e.g., talking about the problem) when presented with stressful social situations. More stable best friendships also predict lower levels of loneliness, bullying, and victimization. Although it is likely that children with the requisite social skills to maintain a best friendship and resolve conflict are also more prosocial and less lonely in general, there is some evidence that having a best friendship offers some protection against victimization. Research shows that children who lose a best friend over the course of a year are more likely to become victimized, but children who gain a best friend over a year are less likely to become victimized.

Although friendship is important for all children, friendship may be especially important for children who experience both normal stress and family- or peer-related stress. For most children, transitioning to a new school can be a stressful experience and friends are emotionally helpful during those times. In fact, successful friendships are as important as home and environmental factors during the transition to school. Other stressors may come in the form of parental changes (e.g., divorce, rejection from parents, harsh parental discipline) or severe rejection from peers. In both scenarios, friendship appears to serve as a buffer against the negative consequences that otherwise might accompany stressful experiences.

Characteristics of Friends and Quality of Friendships

Summarizing decades of research on the characteristics of childhood friendships through meta-analysis, Newcomb and Bagwell (1995) completed the most comprehensive investigation of the components of childhood friendships by comparing friends with nonfriends (i.e., acquaintances, strangers, disliked peers). They concluded that friends spend more time together and engage in more conversation than nonfriends, mostly due to their similar play behaviors and shared activities. Friends and acquaintances look similar in many aspects, particularly in the areas of similarity, equality, and dominance. However, friendships stand out from acquaintanceships because of the unique characteristics of mutual liking, closeness, and loyalty. Although friendships are regarded as generally positive relationships, they are not without disagreement and conflict. While some disagreement is normative, friends, unlike nonfriends, make greater effort to resolve conflicts.

Research interest in the quality of friendship increased during the 1990s. Berndt was one of the first researchers to

identify friendship quality as an individual construct. The construct implies an evaluation and assumes that some friendships are better or worse than others. Friendship quality is typically evaluated as the ratio of positive to negative features. As expected, friendships with more positive features (i.e., closeness, companionship) and fewer negative features (i.e., conflict) are considered higher in quality. Notably, early researchers focused solely on the positive features of friendship. Not until researchers began asking children about the negative features of friendship did they discover that they did indeed exist. While friendships contain positive and negative features, there does not appear to be a strong negative relationship between negative and positive features. In fact, childhood friendships that are high on positive features may be high or low on negative features, such that the two constructs are not mutually exclusive, and often friendships with many positive features also may have many negative features.

Friendship Stability

The stability of friendship refers to the maintenance of the friendship over time. Because friendships are voluntary relationships of choice, they are more likely to end than permanent relationships, like relationships with siblings or cousins. Until recently, most studies assumed that childhood friendships were static and researchers only measured friendships at a singular point in time. As children age, friendship networks expand and evolve to accommodate changing cognitive, social, and emotional development (Poulin and Chan, 2010). This means that some children end a friendship after a few months while others can last over years. Some friendships are easy to replace, while others are much more difficult to replace, if at all. Developmentally, early adolescence appears to represent a unique period when friendship instability peaks, which then stabilizes again during the transition to adolescence. This is likely due to the transition to high school and significant and ongoing biological and emotional development. (More information on adolescent friendship development may be found here (*see* Friendship during Adolescence and Cultural Variations).)

According to Poulin and Chan (2010), several factors affect the stability of a child's friendships. Friendships are more likely to be stable when children form friendships with others who are similar to themselves. Better quality friendships are more stable because a pattern of positive interactions promotes stability. Friendships with more negative features (e.g., higher conflict, rivalry, poor conflict resolution) are less stable. The context of a friendship also impacts stability, such that friendships that overlap across several contexts (e.g., school, extracurricular activities, neighborhood) are more stable over time. Changes in a child's environment disrupt the stability of friendships. For example, when a child transitions to a new school, the stability of existing friendships suffers.

Characteristics Negatively Affecting Childhood Friendship

Some personal characteristics of children inhibit their ability to make friends, keep friends, or maintain high-quality friendships. Children with internalizing problems such as depression are less likely to maintain stable friendships, especially if they exhibit high levels of loneliness. Children with behavior problems, such as aggression, impulsivity, and hyperactivity, also have friendship difficulties. For example, children with attention-deficit/hyperactivity disorder are at high risk for friendship problems due to poor problem-solving strategies (i.e., impulsive, less friendly, and more assertive strategies). Similarly, children with oppositional defiant disorder exhibit problem behaviors among peers, behaving more aggressively when provoked. Finally, children with autism spectrum disorders are at increased risk for social deficits and may experience problems developing and maintaining friendships due to difficulties in approaching same-age peers, engaging in similar conversations, engaging in social reciprocity, and sharing interests.

Cultural Variations

Culture has been defined as a set of values, norms, and practices that shape the individual's behavior. Culture influences children's friendships by structuring the parameters of interactions between peers throughout development. Childhood friendships occur within a dynamic environment where children both learn behavioral expectations dictated by their culture and practice playing out adult cultural roles. Many cultural factors shape a child's life and the nature of his/her friendships, including school structure and extracurricular activities, economic opportunities and socioeconomic status, as well as ideological cultural values, such as collectivism and individualism. These factors strongly influence the nature of friendship and the relative importance of peer relationships in a child's life. While some features of friendship appear to be stable across child development and across cultures, other features differ. Three primary dimensions of friendship (i.e., time spent with friends, reciprocity, and similarity) will be discussed as they relate to similarities and differences across cultures.

Cultural Similarity

Despite the wide range of cultural dimensions that shape childhood friendships, many features of childhood friendship are consistent across the globe (French et al., 2003). Three such stable features of friendships are proximity, reciprocity, and similarity. These qualities influence childhood friendship in every culture, but how each culture emphasizes these characteristics differs.

Friendship typically develops because children are proximal to one another (e.g., same community, school, classroom) and this trend is generally consistent across the globe. However, the type of potential friends who share the same space as a child is influenced by cultural variations. For example, how a child's time is divided between family and peers influences the relative importance that the child places on those relationships. For example, in Kenya most children spend the bulk of their time on family lands, so large families become the primary social sphere for the child (i.e., they are most proximal to the child). Other social opportunities are limited, as parents teach their children to be wary of nonfamily trespassers. In North America, by contrast, children are typically encouraged to be outgoing and social

with nonfamily peers and this behavior is associated with being well-liked and behaving in a culturally acceptable manner. Cultures that place importance on a child spending time with peers and learning to be social with peers send the message to the child that relationships with peers are an important part of childhood. Whatever the cultural context, whether the child spends time with peers or family, close friendships form with the individuals with whom the child spends the most time.

Symmetrical reciprocity has been conceptualized as one of the deep structures of friendship. In many cultures, reciprocity is seen in children sharing with one another and behaving cooperatively. There appears to be a great deal of cross-cultural similarity in this aspect of friendship. For example, both children from Columbia and children from the United States shared more candies with friends than with nonfriends. In every culture, friends have mutual responsibilities to one another, but the exact nature of those responsibilities differs according to the values of the society.

In all cultures, children choose friends who are similar, and friends become more like each other as they spend more time together. Across the globe, childhood friends resemble one another in terms of physical characteristics, such as age, gender, and race, and personal characteristics, such as interests, preferences, and behaviors. Youth who are friends even display similar levels of internalizing symptoms, academic achievement, and aggression (French et al., 2003). Across cultures, children seem to have roughly the same number of friendships, suggesting that children are fairly consistent in the number of peers with whom they can build relationships. This similarity in the number of friends provides some evidence for developmental perspectives on children that emphasize the importance of emotional and psychological development on children's friendship. Furthermore, there appears to be consistency worldwide in the features of children without strong peer relationships. Children without friends seem to consistently display heightened aggression, social withdrawal, and academic struggles (French et al., 2003). Although there are important similarities between cultures in childhood friendship, several factors that vary by culture are examined below.

Classrooms and Extracurricular Activities

For many children across the world, schools are the hub for peer socialization and friendship formation. Children who live in industrialized parts of the world are most likely to go to school and have their friendships shaped by the school structure. The age-segregated style of classrooms and the often age- and gender-segregated style of extracurricular activities strongly influences childhood friendships. Because children tend to form friendships with those with whom they spend the most time, they tend to make friendships with others who are enrolled in the same class, participate in similar activities, and engage in similar style of play. The degree that classrooms and activities are segregated by gender may influence the gender differentiation of friendship. However, there is evidence that youth tend to choose best friends of the same gender as a general rule, no matter the level of industrialization, of the culture, and participation in school of the children. Indeed, a recent meta-analysis on friendship expectations demonstrated that gender differences remained stable across cultures, despite cultural variation in friendship expectations. This suggests that some gender differences in childhood friendship may exist across cultures.

Time with Peers versus Family

Not all children spend significant periods of time at school. Due to economic demands, some children need to work to support the family. In these circumstances, children either become employed or take care of tasks at home so that the parents can work. Compared to children in cultures where school for children is the norm, children who work at home or elsewhere do not experience strict age segregation or separation from immediate family. For example, children who do not attend school often have responsibilities such as caring for younger siblings or working with older siblings in the home, thus primarily spending time being socialized by siblings rather than by nonkin peers. In contrast, in more industrialized countries where both parents tend to work long hours outside the home, such as Taiwan, children tend to spend most of the day at daycare, school, and after-school activities, which may carry on into the evening hours. These activities cause the child to spend considerably more time with peers than with family members, heightening the importance of peer relationships in the child's life.

Children Who Work

Children who must work outside the home to support their families or themselves relate to peers somewhat differently than children whose peer relationships are purely social, because they interact with peers in a work context. The nature of the work itself shapes the setting wherein friends interact, the types of interactions that take place, and the qualities of a friend that are valued. In the Himalayas, friendship responsibilities for leaf-collecting girls include helping each other with physical labor, making work fun for the other, and looking out for the other girl's reputation (Dyson, 2010). The demands of life on the street in Ghana demand that friends are sources of more tangible reciprocity, such as sharing food and resources when they are available (Mizen and Ofosu-Kusi, 2010).

Providing an example of one cultural context where children spend their days assisting the family and the community instead of going to school, Dyson (2010) describes young girls' friendship and work behavior in a small society in the rural Himalayan region. Girls in this remote village spend their days gathering large bushels of leaves to serve as bedding for the livestock. The girls must climb high into the mountains, collect leaves, and then fashion backpacks out of branches to transport the leaves back down the mountain. This job is extremely important for the survival of the community and a girl who can gather and successfully carry a large quantity of leaves is a highly valued member of society. Friends support each other and help each other look good in the eyes of the community. If your friend sees you struggling or believes that you have not yet met the expectation set for you by the community for leaf collecting, she will come to your

aid. In the words of one of the girls, a friend is someone who "doesn't leave me alone in the forest. We collect leaves and wood for each other" (Dyson, 2010).

A second example examines friendships between street children in Accra, Ghana (Mizen and Ofosu-Kusi, 2010). For these children, the cooperative dimensions of friendship are most salient as friends are valued in part for their ability to provide one another with tangible instrumental aid in times of need. Friends are necessary for survival, and fortunately nearly all street-children were able to identify a friend. Being without a friend can mean that you go to sleep on an empty stomach or are left to deal with trouble by yourself, significantly weakening your ability to survive in such a harsh environment. When children were asked to define friendship, there was near consensus that being friends meant helping each other. Friends provide for one another when they are unable to manage on their own and friends can rely on each other when they are in need.

In this way, the cultural context of friendship shapes the salience of the qualities of a friendship. When children are faced with the need to be earners to survive, friends become valued for their helpfulness and hard work, rather than their style of play or interests. In this circumstance, the practical value of friendship (i.e., that we can accomplish more together than alone) becomes essential, but the importance of mutual regard and reciprocity remain. For all children, the nature of friendship is shaped in the context of culture, and friendship is also the avenue through which the values of a culture become reinforced and perpetuated over generations.

Cultural Ideology

The ideological values of a culture add another important layer of cultural influence on childhood friendship. The dimension of collectivism versus individualism is one of the defining constructs of culture. According to Hofstede (1980), traditional individualistic societies place priority on the needs of the individual, whereas traditional collectivistic societies tend to place emphasis on the community as a whole and on the needs of a group. This cultural ideology shapes children's experiences through the dialectal tensions of independence and individualism versus harmony and duty. Not surprisingly, childhood friendships mirror the values of this dynamic. These values are evident in friendship factors such as the degree to which the family is seen as the primary source of companionship and support for a child as compared to peers; and acceptable ways for friends to behave toward one another.

In Costa Rica and South Korea, which are more collectivistic nations, family is considered the most important social realm for a child (Oh, 2008). Support and intimacy are nurtured in the parent–child relationship and sought to a lesser degree from peer relationships. The child from an individualistic culture, as exemplified by traditional Western values, tends to perceive higher social reward (or at least equal social reward) from peers as compared with the family, (Oh, 2008). Children from the United States report receiving significant support, companionship, and intimacy from best friends as compared with parents. Similarly, children in individualistic societies tend to display more independence and less influence from parents in choosing friends as compared with children from collectivistic cultures. Another study compared the reasoning of children from Iceland, traditionally a more individualistic nation, and China, a more traditionally collectivistic nation, when faced with an interpersonal moral dilemma. Findings suggested that Icelandic children tended to make moral decisions based more on self-interest and contractual concerns, as compared to Chinese participants who valued altruistic and relationship-related concerns more highly.

Conclusions

As interest into childhood friendship has advanced over the past several decades, research points to the unique contributions that friendships provide to a child's emotional and social development. The specific components, contributors, and consequences of friendship are multifaceted and fluid and create challenges for researchers to document the theories proposed by early theorists. From early theories, decades of research confirm that childhood friendships should be interpreted from a developmental perspective. From childhood to adolescence, children's friendships mature from a superficial level (e.g., friends chosen based on shared play) to a deeper level (e.g., loyalty and intimacy). Having a best friend is important for a child and the particular characteristics of friendships, such as quality and stability, also have implications for healthy development. Unlike adolescent or adult relationships, childhood friendships are unstable and children may change friends several times in a given year. Neighborhoods, schools, and personal characteristics of the child impact his or her ability to make and keep friends, and some children are better equipped than others to make friends. Despite the intricacies of friendships and the differences between individuals, friendships are beneficial for all children and can be especially important for buffering against the effects of negative life events.

The similarities of friendship in youth across the globe are striking. Children worldwide seek out peers with whom they can become close. Despite the tremendous range of life circumstances in childhood, such as economic demands on the family and the child, the settings where youth spend time, and role of the family in the child's life, childhood friendships are remarkable in their universal significance across cultures and the similarity of their features. Worldwide, children seek peers who resemble themselves, provide mutual support, and spend time together. The differences in friendship across cultures seem to lie in the circumstances of where friendships form, the types of support that are expected from peers, and the qualities of the children and of the relationships that are encouraged. In this way, the children learn the proper societal expectations for relationships with others and practice embodying these characteristics in preparation for becoming successful and social adult members of their community.

Abstract

The functions and prevalence of friendship in infancy and early childhood are described. Methodologies used to study early friendship as well as limitations of extant research are discussed. Also, several studies that use etic and emic approaches to study cultural variations in friendship during early stages of development are noted.

Introduction

In the literature on children's peer relationships, friendship has garnered more attention than all others. The issue of what constitutes a friendship, especially during the earliest years of childhood, has spurred debate that is well beyond the scope of this article. However, we note some relevant aspects of this debate herein.

First, there is widespread agreement that friendship is a *reciprocal* relationship that must be affirmed or recognized by both parties (Bagwell and Schmidt, 2011; Rubin et al., 2006). Reciprocity is the factor that distinguishes between friendship and the nonreciprocal attraction of only one partner to another. A second defining characteristic of friendship in early childhood (and beyond) is mutual *affection* (Rubin et al., 2006). The interdependence of the two partners derives primarily from socioemotional rather than instrumental motives. Third, friendships are *voluntary*, not obligatory or prescribed. In some cultures, children may be assigned their 'friends,' sometimes even at birth (Krappman, 1996). Although these relationships may take on some of the characteristics and goals of voluntary relationships, most scholars would agree that by not meeting the criteria of reciprocal choice and mutual affection, their involuntary nature argues against confusing them with friendship.

The mutuality of friendship and the autonomy children have in choosing their friends has long intrigued developmental scientists. For example, Sullivan (1953) believed that the understanding of mutual respect, equality, and reciprocity developed from social experiences of chumships. Sullivan's theory has proved influential in the contemporary study of children's friendships as well as in the understanding of the negative psychological consequences of not having close dyadic relationships with friends (e.g., Wojslawowicz et al., 2006).

The aims of this article are twofold. First, we trace the early development of friendship from infancy through early childhood. Second, we discuss the importance of cultural influences on the processes and outcomes associated with friendships in early childhood. Before engaging in either pursuit, it is important to highlight the developmental significance of friendship and to examine how it is that friendship is assessed in the earliest years of childhood.

The Developmental Significance of Friendship

Human beings are innately social creatures, driven by a fundamental need to belong and form lasting attachments. This drive first manifests in the attachment relationship formed between an infant and his or her primary caregiver (Bowlby, 1969). As children age, they are able to interact socially with an increasing array of individuals, including peers. Given the opportunity, almost all children form friendships. Even a large majority of socially withdrawn children have at least one mutual friend (Rubin et al., 2009). The ubiquitous nature of friendship suggests that it may be evolutionarily adaptive. Friends can provide both instrumental and emotional support (Rubin et al., 2006), and indeed friendship analogs have been found in other social species (see Seyfarth and Cheyney, 2012; for a review).

One significant aspect of friendship is *prevalence*; that is, how many friends does a given child have? Another important aspect of friendship is involvement; does the child have at least one mutual friendship or do none exist? Generally, children who have friendships fare better than those who do not. For example, as early as the period of transition into elementary school, children who are lacking in friendship are at greater risk for the development of adolescent loneliness and depression than those who have a friend (Pedersen et al., 2007). There are at least two reasons that having a friend is associated with more positive outcomes. First, as noted above friends can be sources of support and comfort, thereby buffering the effects of stressors. Second, as interaction partners, friends provide opportunities to improve social and emotional competence and to avoid psychological maladaptation (Rubin et al., 2006).

The Assessment of Friendship in Infancy and Early Childhood

From the time children enter preschool (age of 3 years), researchers can rely on several techniques to identify friendship dyads. For example, parents and teachers can be asked with whom it is that children play with most often. These reports can be especially useful in confirming friendship with children who do not attend the same preschool or child care center, but reside in the same neighborhood. However, a noted caveat to using parent-report is that it may be more indicative of who the parent prefers their child befriend and spend time with (Howes, 2009).

Ofttimes, preschoolers are provided with pictures of all their classmates and are asked to identify the peers they like the most or with whom they most often play. Typically, researchers may use the child's top three choices of preferred playmates or friends (Rubin et al., 2006). When using such sociometric procedures, it is necessary to assess *mutual preference*; thus

a friendship is one in which two children choose each other as the most preferred playmate.

Of course, during infancy and toddlerhood, when communication skills are rather limited, sociometric procedures cannot be used. Instead, in addition to parent and teacher reports, researchers have come to rely on observational procedures to identify preferred dyadic relationships. Observational methods are particularly useful because they allow researchers to watch for more nuanced behaviors that may not be measurable with standard questionnaires or interview techniques. Thus, observations have been used to identify peers who frequently seek each other out, spend significant time together (in close proximity), and share positive affect at levels greater than chance probability (Howes, 2009).

Friendships in Infancy (0–2 years)

Infants do not have friendships as traditionally defined and measured later in childhood. In many cases, infants lack the opportunities to interact regularly with peers, and even when they do, their limited communication skills hamper friendship formation. Still, some researchers contend that infants have the capacity for rudimentary friendships. By 6 months, infants begin to more consistently orient toward peers and engage in longer interactions, often centered on toys and other simulating objects in the environment (Hay et al., 1983). During the second year, infants increasingly play with a partner rather than alone, and they appear to prefer peers as interaction partners over adults (Eckerman et al., 1975). Although infants are less likely to demonstrate positive affect or engage in complementary play compared to toddlers and preschoolers, they nevertheless show clear preferences for specific social partners.

For example, by observing infants and toddlers during play, Howes (2009) has found evidence that mutual friendships can be identified. In observational studies of very young children, behavioral indices of mutual affection, companionship (assessed by the frequency of observed proximity to specific peers), complementary play (e.g., rolling a ball back and forth), and relative frequency of initiations directed to and received from specific peers are used as markers of friendship.

Significantly, although the friendships of infants and toddlers do not involve such features as intimate disclosure, validation, and instrumental aid, it is nevertheless the case that infants and toddlers who have opportunities to regularly interact with peers are more socially competent at the age of 4 years than their counterparts who have few such experiences (Howes, 1991).

Summary

During the infant and toddler periods, friendships, as construed by the constructs noted above (mutuality, reciprocity, positive affect), do appear to exist; however, it is doubtful that they carry the same strength of psychological meaning as the friendships of older children. Nevertheless, these early relationships may lay the groundwork for the establishment and maintenance of friendships throughout the childhood years (Dunn, 2004).

Friendships in Early Childhood (2–6 Years)

The function and prevalence of friendship in early childhood is distinctly different from the social interactions of infants. During early childhood, friendships are primarily rooted in the principle of *homophily*. Homophily refers to the notion that individuals are attracted to others who are similar to them in some noticeable regard; in effect, homophily is the "birds of a feather flock together" principle. For example, similarities in age, race, and sex draw young children together (Aboud and Mendelson, 1996; Howes, 2009). Homophily also extends to behavioral characteristics; preschoolers are drawn to others who engage in similar play behaviors and prefer similar activities and materials. Furthermore, it has been shown that aggressive children tend to befriend other aggressive children, and withdrawn children tend to befriend other withdrawn children (Rubin et al., 2006).

The Understanding of Friendship

Unlike infants, young children are able to communicate what they know about the construct of friendship. Young children tend to perceive friendship as comprising the spending of significant time with a preferred other who engages in activities that are pleasant, and who have access to materials that are fun to play with (Bigelow, 1977). Friends help each other, have similar interests, share preferred possessions, cooperate on tasks, and play together (Dunn, 2004). Gottman (1986) audio recorded children aged 3–6 as they played with a best friend. When transcribing the conversations, it was confirmed that the friendships were strongly based on mutual likes and dislikes. The recordings also provided evidence of early instances of self-disclosure. Thus, as early as the preschool years, a friend represented someone who could be trusted with knowledge of one's personal beliefs, desires, or fears.

Play and Friendship

Play is an essential component of friendships in early childhood. During this period of development, most friendship activities consist of play. However, play is not a frivolous activity to be overlooked or dismissed. By 24 months, children are able to engage in *intersubjectivity* during play – the ability to share meaning during pretense (Trevarthen, 1979). That is, children are able to take on imaginary roles, while doing so in a rule-governed context. Sociodramatic play becomes more frequent during the preschool years, and is purposeful in that it allows children to challenge and take on different social roles and identities (Dunn, 2004). Children who have friends are able to more seamlessly enter playgroups, and have more complex social pretend play. The increasing frequency of play aids in the maturation of such social cognitive abilities as theory of mind (perspective-taking or being able to understand the thoughts, feelings, and visual viewpoints of others) and hypothetical-reflective reasoning (e.g., social information processing), which provide a basis for the development of social and emotional competence (Rubin et al., 2011).

Preschoolers' social interactions with friends are distinct from their behavior with other children who are familiar but not friends. For example, children as young as 3.5 years

direct more social overtures, engage in more social interactions (including sociodramatic play), and interact in more cooperative and prosocial ways with friends than nonfriends (e.g., Dunn, 2004).

Conflict and Friendship

Conflict occurs more frequently among preschool friends than among familiar or unfamiliar nonfriend peers. For example, researchers have noted that preschool friends demonstrate more quarreling and more active (assaults and threats) and reactive (refusals and resistance) hostility than nonfriends. These seemingly curious findings are best understood by recognizing that friends spend much more time actually interacting with each other than do nonfriends (Rubin et al., 2006). However, it is also the case that children are more likely to negotiate and compromise until a solution is reached with friends, compared to nonfriends (Howes, 2009). Furthermore, children are more likely to reach equitable resolutions and have mutual agreements with friends than nonfriends. In conflict outcomes, friends are more likely to have equal resolutions, relative to win or lose occurrences. Also, following conflict resolution, friends are more likely than neutral associates to stay in physical proximity and continue to engage in interaction (Hartup, 1996). These increased instances of compromise, negotiation, conflict resolution, and positive affect in early friendships have been proposed to influence the development of self-regulation and affect (Bagwell and Schmidt, 2011).

The Prevalence of Friendship in Early Childhood

Approximately 75% of preschoolers have reciprocally nominated best friendships (Bagwell and Schmidt, 2011). However, not all friendships in early childhood are equally stable and not all young children have a best friend (Ladd et al., 1996). Those friendships that involve higher levels of positive friendship qualities (e.g., validation) and lower levels of negative friendship qualities (e.g., low conflict) are most likely to be stable.

Importantly, during early childhood, the ability to make friends, friendship quality, and stability of young children's friendships are associated with, and predicted by, social cognitive and emotional maturity. For example, the abilities to perspective-take are associated with friendship formation, friendship maintenance, and friendship quality (Dunn, 2004). Furthermore, the young child's ability to regulate emotions is associated with, and predictive of, both the number of mutual friends and friendship quality (Walden et al., 1999).

Adjustment and Friendship

Friendships in early childhood have been found to promote positive adjustment. For example, children who start the academic year with a friend have more positive feelings regarding school. Ladd and colleagues (e.g., Ladd et al., 1996) found that children with many friends at the time of elementary school entry developed more favorable attitudes toward school in the early months than children with fewer friends. Those who maintained their friendships liked school better as the year went by. Findings also revealed positive associations between children's perceptions of best friendship quality in kindergarten and later indices of scholastic adjustment (school-related affect, perceptions, involvement, and performance) in grade school. It is clear that the benefits gained from friendships in early childhood are extensive.

Research Gaps: Early Friendships

First, and perhaps most notably, extant research has generally failed to examine the development or maintenance of early close friendships. Although peer relationships are vital to early social development, close friendships can provide children with a sense of companionship and security that facilitates enhanced social competence and emotional growth, particularly during early childhood (Howes, 2009). Friendships also buffer children from loneliness and social dissatisfaction and provide a social context to help children develop loyalty and commitment toward other social partners. Early friendship *quality*, often predicts children's long-term psychosocial adjustment (Rubin et al., 2006). Thus, in the future, researchers should study friend-specific relationships in addition to peer acceptance, rejection, and children's social behavioral proclivities.

A second limitation of extant research involves the failure to assess reported and observed friendship *quality* among *mutually* nominated friends or best friends. Assessing perceived friendship quality from the perspective of a single member of a putative friendship dyad poses a number of methodological limitations. For one, relying on the perspective of a single member of the dyad provides a one-dimensional view of the relationship. It could be the case that children may inadvertently overestimate or underestimate the quality of their friendships. Thus, it would behoove researchers who are interested in examining the significance of friendship quality to rely on information provided by both members of the reciprocally nominated friendship pair. In addition, researchers should increasingly rely on observations of friendship quality during naturalistic interaction, especially during the early years of development.

Cultural Variations in Early Friendships

Defining Culture

Culture may be defined as the set of attitudes, behaviors, beliefs, and values shared by a group of people. Members of a cultural group communicate shared perspectives from one generation to the next, with younger children learning about cultural norms from older members of a society (Matsumoto, 1997). Since most individuals in a cultural group share beliefs and customs, scholars view the development of 'typical' cultural behaviors as adaptive to children who are fitting into a larger group with established norms. In comparison, children who do not develop the normative identity of their cultural group are thought to demonstrate maladaptive behaviors that may hinder the child's acceptance by other members of the culture.

Cross-Cultural Research Approaches

Culture is primarily studied using two research approaches. The first, an 'etic approach,' assumes that behavioral constructs

(i.e., concepts, methods, measures) studied in one culture have significance in all other cultures. Alternatively, an 'emic approach' describes the study of cultural norms that are specific to one group of people or within one culture. Studies using an etic approach require researchers to develop, test, and analyze constructs in the same manner across groups. As a result, findings may overlook specific cultural perspectives or culturally specific behavioral nuances. For example, researchers using an etic approach may assume that friendship 'looks' the same in all cultural groups, and would likely assess friendship processes by asking the same research questions and methodologies in all groups. Scholars using an emic approach assume that their cultures may not share the same attitudes, behaviors, beliefs, or values about friendship and may tailor empirical questions or methodologies to specific cultural groups. One example of emic research could involve the comparison of friendship processes and provisions in Western (or relatively independent, individualistic) cultures versus more interdependent, collectivist Eastern or Southern cultures. In this case, an emic approach would entail the use of culturally adapted instruments and observational coding schemes to ensure the collection and analysis of culture-specific information about children's friendships.

Using both etic and emic approaches, scholars can help distinguish those research constructs that are universally meaningful and those that are culture specific. It is likely that aspects of many constructs, such as friendship, may support the etic and emic perspectives. That is, some elements of friendship may be viewed as universally held while others may be unique to particular cultural groups.

Friendship versus Familial or Community Relationships

Young children from Western cultures in North America and Europe are often encouraged to develop and nurture friendships in addition to caring for and respecting family members; indeed, children from Eastern and Southern countries such as South Korea and Cuba have been found to form close, dyadic friendships that last into adulthood (Chen and French, 2008).

In comparison, some cultures place a stronger emphasis on early family or community relationships rather than on extrafamilial friendships. For example, young children from Yucatec Mayan communities rarely form close friendships with children outside of the immediate and extended family. In fact, Mayan 'friendships' are typically close relationships between children and their same-age siblings or cousins (Gaskins, 2008).

Community-level relationships are a priority among children in Israel. Rather than spending time with close friends, children from kibbutz communities are immersed in group activities and community events at a very early age (Sharaban, 2006). Due to cultural emphases on group relationships in Indonesia, Javanese children also have multiple important relationships with nonfriend members of the community rather than dyadic friendships (French et al., 2005).

Shared Activities

There is cultural variation in the types of activities in which young children participate. In Western contexts, play is a primary focus of peer interactions and friendship during early childhood. Young children from Western cultures often use toys, games, or imaginative role-play activities to guide interactions with friends. In some cultures, however, children's play is not viewed as important as observing others or learning about work responsibilities (Gosso and Carvalho, 2013). These cultures are usually ones in which dyadic friendship is not valued above relationships within the family unit or community. For example, young Yucatec Mayan children who typically do not form relationships outside of immediate and extended family networks spend most time engaged in maintenance activities (i.e., eating, sleeping, grooming) and the observation of activities occurring within the family compound (Gaskins, 2008). In Mayan culture, childhood play is a tertiary activity since it is believed to compete with adult work goals. When play does occur, young Mayan children rarely participate in symbolic or 'pretend' play with same-age children, instead engaging in play through the manipulation of objects or production of large motor movements.

The Giriama of Kenya believe it is important to teach children about shared work responsibilities. Giriama children typically 'peak' in peer interactions at around the age of 5 years, with children's social time gradually giving way to errands, infant caregiving assistance, and adult-focused work tasks (Wenger, 2008). Throughout their lives, however, Giriama males prepare for the role of '*mwenye mudzi*,' a person who has learned to balance dominance and sociability in the Kenyan patriarchal society. Therefore, among Giriama children, young boys are provided with more unstructured social time than girls, and this divergent allotment of social time lasts through adolescence and into adulthood. For this reason, Giriama males have more opportunities to develop and maintain close familial, peer, and community-level relationships than females.

Intimacy

In many cultures, friendship is defined by mutual trust and feeling sufficiently secure to share personal information with a peer. Around the world, however, not all friendships take on the same characteristics of intimacy. In some Alaska Native villages, it is culturally inappropriate to discuss sensitive topics, regardless of whether a child wishes to share this information with a friend or nonfriend. In these cases, silence may be more indicative of mutual understanding and/or respect than the sharing of information (Gudykunst, 1998). In contrast, young children from Eastern and Southern cultures such as South Korea and Cuba are often described as having cultural values that exemplify group harmony and intimate relationships. Individuals from South Korea and Cuba describe the exchange of intimate information exclusively within a dyad as the most important characteristic of friendship and suggest that friendship is crucial for societal success (Triandis et al., 1988). Researchers have shown that young children from these two countries value intimacy more than children in North America (Gonzalez et al., 2004; French et al., 2006).

Conflict

As previously noted, since friends spend more time together than nonfriends, there are more opportunities for conflict

(Newcomb and Bagwell, 1995). In North America where assertiveness and competition are prominent cultural values, parents encourage young children to negotiate or 'work out' problems with friends (Rubin and Menzer, 2010). Young children are viewed as developmentally skilled if they are able to resolve interpersonal conflicts because individuals from Western cultures often view the 'friendly' disagreements in early childhood as practice for navigating discord later in life.

In Italy, friendships are wrought with what others may perceive as extreme conflict and disagreement. At a very young age, Italian children begin to engage in '*discussione*,' or lengthy verbal exchanges with same-age peers (Corsaro and Rizzo, 1988). *Discussione* includes intense 'debates and points of contention about various aspects of children's social worlds' as well as the accuracy of previous conversations between the children. To some, this may appear as if one child is 'picking on' another, but *discussione* is viewed as normative in many Italian families. Further, *discussione* is often perceived as a process by which young, preschool-aged friends use conflict to help each other learn about the adult world and advance through development.

In contrast to young Italian children or those from North American and other Western European countries, children from East Asian cultures tend to disengage from conflict instead of mediating or debating about disagreements (Xu et al., 2006). In China, for example, young children practice '*ren*,' also known as forbearance, during times of animosity. The self-control and restraint associated with *ren* helps promote group harmony and tolerance of others with conflicting viewpoints, a social skill that is important in East Asian societies. Thus, in some areas of the world, the active withholding of disagreement may be more salient in close friendship than conflict.

Psychosocial Outcomes

Several researchers have demonstrated that children with positive quality friendships also have higher self-esteem and lower levels of childhood internalizing and externalizing problems, such as depression, anxiety, aggression, and/or other delinquent behaviors (Rubin et al., 2006). However, much of the extant research about the positive outcomes of early friendship involves children from Westernized countries.

In other areas of the world, close friendships are not always predictive of higher self-esteem. For instance, having close friends is not directly associated with self-worth among Chinese, Indonesian, Arab, or Caribbean children (Chen and French, 2008; Dayan et al., 2001). Scholars suggest that this cultural disparity is related to overarching socialization values and ideals. If children are tasked with making friends and being socially competent members of society (as in Western cultures), the failure to achieve such cultural goals will contribute to lower levels of self-esteem. In cultures where fitting into social situations is not a primary cultural requirement, children without friends will not develop a poor sense of self (Chen and French, 2008).

Social scientists suggest that young children may exhibit more internalizing and externalizing behaviors in societies that value independence, competitiveness, and assertiveness because it is acceptable to acknowledge individual concerns in individualistic cultures (Cole and Tan, 2002). In contrast, for children from countries that value cooperation and self-control, such as India or other Eastern Asian countries, it may be culturally inappropriate to disrupt group processes by focusing on personal sentiments (Wilson et al., 2012). Therefore, it is argued that children without friends from Western cultures may display poorer psychosocial outcomes than children from Eastern or Southern cultures because it is more acceptable to have or report such behaviors in regions of the world that value expression over self-restraint (Cole and Tan, 2002; Wilson et al., 2012).

Research Gaps: Early Friendship and Culture

In addition to the aforementioned limitations of research about friendship during infancy and early childhood, there are gaps in the literature about early friendship and culture. Most studies have used an etic approach and empirical instruments developed in Western countries to study cross-cultural variations in friendship. In order to most accurately study culture and friendship, however, researchers should consider using an emic perspective in their cross-cultural or cultural studies. In particular, scholars should analyze reported and observed indicators of friendship using measures and methodologies coconstructed with local stakeholders and cultural experts.

Another limitation of extant research involves the generalization of studies within a society. In the United States, for instance, children grow up in rural, suburban, and urban areas, and such contexts may provide within-culture variations in friendship values and ideals. Thus, researchers would do well to investigate within country 'subcultures' in an effort to appropriately depict the nature of early childhood friendships.

Conclusion

In this article, we have focused on the function and prevalence of friendship in infancy and early childhood. We discussed the methodologies used to study early friendship as well as limitations of extant research. Also, we highlighted several studies that used etic and emic approaches to study cultural variations in friendship during early stages of development. Despite the information currently available about early friendships, additional studies are required to explore characteristics of young children's friendships. Furthermore, cross-cultural researchers are tasked with using dyadic, observational, and emic methodologies to comprehensively explore within- and across-culture variations in friendship during infancy and early childhood.

Friendship Experiences of Lesbian, Gay, Bisexual, and Transgender Individuals

MP Galupo, Towson University, Towson, MD, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Friendships can play an important role in the lives of lesbian, gay, bisexual, and transgender (LGBT) individuals. LGBT friendship patterns and experience have been shown to vary across sexual orientation, gender, gender identity, and race. Friendships also differ based on whether or not friends identify as part of the LGBT community. LGBT individuals often think of their friends as 'families of choice' as friendships take on increased significance when traditional support from family and community may not be consistently offered. In addition to having their own unique benefits, friendships with individuals outside of the LGBT community have been seen as important in the development of heterosexual allies to the LGBT community.

Historically, research on the relationship experiences of lesbian, gay, bisexual, and transgender individuals (LGBT) has deemphasized friendships in favor of focusing on 'primary' or romantic relationships (Weinstock, 1998). Friendships, however, can play an important role in the lives of LGBT individuals. In many ways, the friendship experiences of LGBT individuals are similar to the friendships of their heterosexual counterparts where LGBT and heterosexual individuals report a similar number of close friends (Galupo, 2009). Despite similarities to heterosexual friendships, friendship patterns and experience have been shown to vary across both sexual orientation (Galupo, 2007a, 2009; Ueno et al., 2012) and gender identity (Hines, 2007; Galupo et al., 2014). Among sexual minorities, friendship patterns have also been shown to differ across gender (Baiocco et al., 2012; Galupo, 2007a) and race (Galupo, 2007a).

Friendships are considered to have increased importance for LGBT individuals as friendship is emphasized during times of social change and is particularly salient for individuals when their identity is at odds with social norms and during times of transition (Weeks, 1995). The importance of friendship is underscored by the fact that when LGBT individuals first 'come out,' the majority make that first disclosure to a friend. Coming out to friends can be associated with positive outcomes such as strengthening feelings of trust and acceptance. It can also be met with negative reactions and outcomes, leading to loss of relationships or the creation of emotional distance within the relationship. Either way LGBT individuals experience friendship as a means of social support, which may take on increased significance when traditional support from family and community may not be consistently offered; LGBT individuals report less discrimination in the context of friendship than with their families of origin (Takács, 2006). Friendships, may thus take on additional importance by fulfilling a supportive role in relation to minority stress and status.

Scholars consider friendships to be distinct from other types of social relationships in that they are voluntary relationships constructed around reciprocity, mutuality, and equality. Research on friendships between LGBT individuals emphasizes that these friendships are particularly important because they represent a social relationship in which individuals can experience relative equality. For example, in his research on friendships between gay men, Nardi (1999) describes how these friendships can provide opportunities for gay men to experience equity not easily achieved in other friendships where social identity is being bridged and where differences in sexual orientation or gender require constant negotiation. Nardi's research underscores the importance of understanding the way in which friendships of LGBT individuals are impacted by broader cultural attitudes and how these broader social context impacts are experienced at a social and personal level. In particular, it is important to understand intersections of identity among social groups when considering the social and personal relationships of LGBT individuals. Friendships have been shown to be simultaneously impacted by sexism, racism, heterosexism, biphobia, and transphobia (Galupo, 2006; Galupo et al., 2014); not all LGBT individuals have the same experiences in friendship.

Looking at LGBT friendships in more depth, LGBT friendships have been examined using multiple perspectives including classifying friendships based on closeness with distinctions made between casual, close, and best friends (Baiocco et al., 2012; Galupo, 2009) and addressing friendship in the context of friendship dyads (e.g., Galupo, 2007b; Price, 1999), groups or networks (e.g., Tillman-Healy, 2001), and larger communities (e.g., Esterberg, 1997; Hines, 2007; Nardi, 1999). Although not always described as friendship analysis, these perspectives have been included in the research on most interpersonal relationships of LGBT individuals and are thus illustrative of LGBT friendships.

Friendships within the LGBT Community

Friends as Family

LGBT friendship research has mostly focused on understanding friendships that form between individuals who identify within the LGBT community. Consistent with the notion of homophily (the idea that individuals connect with others who are similar to themselves) lesbians and gay men form the majority of their friendships with individuals of the same sex who also identify with the LGBT community (Galupo, 2007b, 2009) with lesbian women befriending other lesbians (Stanley, 1996) and gay men befriending other gay men (Nardi, 1992, 1999). LGBT friendship

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10214-4

is often characterized as providing a unique type of familial support (Nardi, 1992; Weinstock, 1998; Hines, 2007) where friendships function as 'families of choice' (Weston, 1991) and serve to buffer LGBT individuals from social isolation or rejection associated with homophobia, biphobia, and transphobia. That LGBT individuals consider others within the community in familial terms is evidenced by the use of the colloquial term 'family' to refer to other individuals in the community.

Within LGBT communities, friendships are often characterized as social networks that make up the larger LGBT (Esterberg, 1997; Tillman-Healy, 2001) and transgender (Hines, 2007) communities and thus allow individuals to positively experience their lesbian, gay, and bisexual (LGB) or transgender identity (Riggle and Rostosky, 2011). These within-community friendships are seen as having unique benefits as they may provide a sense of shared experience and an avenue for processing minority status. Within-community friendships can provide a buffer against being socially devalued as a sexual minority and can provide an outlet for sharing daily aspects of life, especially for individuals who are not generally open about their sexual orientation identity (Stanley, 1996). LGBT friends can also serve as role models in a culture where LGBT experience is not widely visible.

While lesbians and gay men may find a unique type of support through same-orientation friendships, bisexual women and men are less likely to do so. Bisexual women and men are less likely to have a friend with the same (bisexual) identity as themselves (Galupo, 2007a) and report that their bisexual identity is often not acknowledged within their cross-orientation friendships with heterosexual (Galupo, 2007b) and lesbian/gay (Rust, 1995) individuals. Similarly, LGBT individuals of color are faced with simultaneously negotiating sexual orientation and race in their friendships (Galupo, 2007b; Hall and Rose, 1996) and their pressure to choose one identity over the other is likely to impact their experience of friendship.

Transgender Friendships: Friends as 'Family' and as 'Community Resource'

In many ways, lesbian and gay within-community friendships generally serve as a proxy to family relationships. They can provide a sense of belongingness and shared culture that may not be fulfilled by families of origin. Friends can serve as 'families of choice' by providing emotional support not provided by lost or strained familial relationships due to differences in sexual orientation. Transgender friendships, likewise, fulfill a similar familial role. However, the stigma and marginalization experienced by transgender individuals is even more pronounced than for LGB individuals. Even though LGB and transgender individuals are generally conceptualized as a unified group, transgender persons often experience additional stigmatization and discrimination, are pathologized within the medical community, and do not enjoy the same legal protections afforded to sexual minorities (Lev, 2004). Even within the LGBT community, transgender individuals and issues related to gender identity have a history of being overshadowed by the LGB community. Taken together, transgender individuals are more likely to be subject to social isolation and invisibility.

It makes sense, then, that friendships take on an additional level of significance for transgender individuals. Transgender friends are generally characterized as having an understanding of nonnormative experience; are knowledgeable on issues of gender, sex, and privilege; are nonjudgmental/open-minded; and offer a relationship in which transgender individuals can feel comfortable being themselves and talk about transgender issues (Galupo et al., 2014). In short, these friendships provide a shared sense of belonging, family, and community.

While providing support and having similar experiences are regarded as characteristics of friendship in general, transgender individuals describe these benefits primarily in relation to decisions and experiences surrounding transitioning and in ways that are specific to transgender experience (Hines, 2007). Transgender friends are also seen as providing needed counseling unavailable from the traditional health care system. Benefits of friendships with other transgender individuals are largely seen as filling in the gaps of support and services not otherwise provided by traditional family, friends, and institutions. In particular, transgender–transgender friendships have been shown to have unique benefits not experienced to the same degree with LGB individuals. When compared to their friendships with LGB individuals, transgender individuals find that with their transgender friends they are more likely to have shared experiences, be able to talk about transgender issues, receive support via mentoring and shared resources, and are more comfortable being themselves (Galupo et al., 2014).

Friendships, Romance, and Sexuality

In the general literature, friendships are often explicitly distinguished from romantic relationships and sexual interest. The platonic nature of friendships, then, is assumed to provide a unique type of relationship. However, the LGBT friendship literature from the beginning has suggested that the same distinctions may not hold for LGBT individuals. Rather, LGBT friendships may defy traditional heterosexist definitions of friendships in important ways (Rose, 2000). Friendships of LGBT individuals may not be void of romantic feelings and have sometimes even been described as 'love relationships' (Kitzinger and Perkins, 1993). For LGBT individuals, friendships have been seen as the most common relational context in which romantic relationships develop (Herdt and Boxer, 1996) where many LGB individuals report having first been friends with their partner before becoming romantically involved (Rose and Zand, 2002). Likewise, LGB individuals when asked about their friendships often count lovers and exlovers among their close friends (Clunis and Green, 2000; Weinstock, 1998).

Passionate friendships have also been described in the literature as developing most often out of best same-sex friendships where intense emotional relationships develop in ways similar to romantic relationships but lack a sexual component (Diamond, 2002). Although more likely to be studied among young lesbian and bisexual women, friendships can lead to intense emotional interactions that incorporate elements of both friendships and romantic relationships for LGB women or men. It is also important to note that passionate friendships are not necessarily exclusively experienced by individuals who identify as sexual minorities (Diamond, 2002).

Clearly, the research on friendships of LGBT individuals emphasizes that friendships can include elements similar to romantic relationships. Likewise, friendships may also include elements of sexual interest (Diamond, 2002; Herdt and Boxer, 1996; Rose and Zand, 2002). For example, friendships may begin first with sexual interest and activity and then later develop into friendship (Nardi, 1999; Weinstock, 1998). In addition, casual friendships may encompass sexual activity without a romantic component and friendships may also serve as a site for identity development as it relates to sexual exploration (Morgan and Thompson, 2006).

Friendships Outside the LGBT Community

Friendships outside the LGBT community are tenuously constructed around a number of barriers. Barriers include the stigma of having an LGB friend, sexual tension, and reduced comfort for both the LGB (Price, 1999) and heterosexual (Mohr and Sedlacek, 2000) individuals in the friendship. Although bisexual individuals are more likely to have cross-orientation friendships with heterosexual individuals (Galupo, 2007a), these friendships exist at the cost of bisexual identity where issues related to bisexual identity are not always acknowledged within the friendship (Galupo, 2007b).

Benefits of friendships of LGBT individuals with others outside the LGBT community have also been considered. For example, lesbian and bisexual women report that through their friendships with heterosexual women they gain an understanding that acceptance from heterosexuals is possible, gain an objective perspective in their lives, are able to break down stereotypes, and experience increased closeness and trust within the friendship accompanying sexual orientation disclosure (Galupo and St. John, 2001). Muraco (2012) discusses ways in which friendships with heterosexual individuals can function as 'intentional families' for both LGB and heterosexual men and women.

The literature on the friendships of transgender individuals also details a variety of benefits to friendships outside of the LGBT community. These include fostering a feeling of normalcy, offering more diverse perspectives and interactions, helping transgender individuals to present as their identified gender, as well as validating transgender identity and experience. Additionally, these friendships provide an opportunity to educate others about transgender experience (Galupo et al., 2014).

Friends as Allies

Friendships outside the LGBT community provide both LGB and transgender individuals the opportunity to educate individuals about LGBT experience and discrimination. Friendships, then, may be an important avenue for developing allies to the LGBT community. The research literature has long connected interpersonal contact – inclusive of friendship – as being related to positive attitudes toward LGBT individuals. More recently, friendships with LGBT individuals has been more directly conceptualized as important in the development of heterosexual allies to the LGBT community (Duhigg et al., 2010; Fingerhut, 2011). LGBT allies can serve to both personally support LGBT individuals and advocate for larger acceptance and rights of LGBT individuals.

Conclusion

Friendship experience of LGBT individuals challenges the notion of friendship as secondary to romantic relationships. The emphasis on friends as 'family' (chosen family) illustrates that for LGBT individuals friendships both within and outside the LGBT community serve important roles. Research on the experiences of individuals within the transgender communities indicate that friendship fulfills even a broader role by providing support and services not otherwise provided by traditional family, friends, and institutions. Likewise, friendships with individuals outside the LGBT community provide a sense of acceptance and an opportunity for developing allies to the LGBT community. Although the research emphasizes a unique and potentially broader role of friendship for LGBT individuals when compared to their heterosexual counterparts, it is important to note that this is, in part, due to the fact that friendships are experienced within a larger system of discrimination and inequality still present in family and other societal institutions.

Abstract

This article presents an analytic history of the legacy of Erich Fromm, the German psychoanalyst, social psychologist, critical thinker, best-selling author, and an early member of the Frankfurt School. Fromm's intellectual insights flowed from aspects of his life and optimal marginality in relationship to various intellectual social movements and his complex relationship with the Frankfurt School. But Fromm also became a 'forgotten intellectual' for some of the same biographical and sociological reasons. Ideas and scholarly influence can rise again as well as decline, so with his contemporary relevance in mind, we will discuss some of the underappreciated contributions Fromm made to the study of authoritarianism, race, and ethnicity as well as his influence on theories of gender and the practice of public sociology. There is new interest in Fromm's work, suggesting that he might find again a place in the history and contemporary scholarship in social psychology, sociology, critical theory, and psychoanalysis.

Introduction

Erich Fromm (1900–80) was a German psychoanalyst, social psychologist, critical social thinker, social activists, best-selling author, and a public intellectual. He was first recognized for his original analysis of the rise of the Nazi movement in the 1930s presented in *Escape from Freedom* (1941), a book where he creatively connected Marxist, Freudian, Weberian, and existentialist insights. In subsequent years, he wrote such best sellers as *The Sane Society* (1955), *The Art of Loving* (1956), and *To Have or To Be?* (1976) and returned to academic scholarship in *Social Character in a Mexican Village* (1970) (with Michael Maccoby) and *Anatomy of Human Destructiveness* (1973). Popularity among wider audiences, however, gradually undermined Fromm's recognition among academics, especially after he was ostracized from psychoanalysis and air brushed out of the 'origin myths' of early Frankfurt School 'critical theory,' rendering him a forgotten intellectual (McLaughlin, 1998, 1999).

Fromm's position of 'optimal marginality' (McLaughlin, 2001b), in his professional as well as private life, allowed him to become well acquainted with numerous theoretical perspectives and to acquire skills for effortlessly maneuvering between different intellectual networks, movements, and social groups. Fromm was trained in Germany, bringing to America European Marxist, Freudian, and Weberian theories, but he also integrated into and learned from American culture and intellectual life more than most other émigré intellectuals of his generation. What resulted from the combination of Fromm's training and wide reading, his sociological 'optimal marginality,' and his cultural border crossing, was an eclectic theoretical stand, a compelling ethical vision, and a jargon-free language that reached different publics around the world.

We will first discuss Fromm's personal life and career and then we will highlight the relevance of his ideas to contemporary social science scholarship. We will present the largely unacknowledged intellectual contributions he made to the three fields of study (authoritarian personality research, race and racism, and gender studies) and discuss the pioneering role he played in mid-twentieth-century development of the role of the public intellectual and public sociologist, two overlapping models for intellectuals that are being widely debated today.

Fromm's Personal Life and Career

Fromm was born in 1900 to a middle-class Orthodox Jewish family. The loveless marriage his parents were trapped in created an environment whereby Fromm became a neurotic child (Burston, 1991). Overcoming obstacles, young Erich studied under prominent rabbis and acquired intellectual tools he used to challenge his parents' worldview. After abandoning a plan to become a rabbi himself, Fromm enrolled at the age of 17 years at the university in Heidelberg, where he was mentored by Max Weber's younger brother, Alfred Weber. Fromm's doctoral thesis (1922) analyzing three Jewish sects ability to follow their religious traditions without receiving any institutional support (Ortmeyer, 1998) was essentially a social psychological work focusing on the influence of social forces on the lives of individuals, a reappearing theme in Fromm's books. Impressed by his thesis, Weber encouraged Fromm to pursue an academic career, a plan he rejected because he wanted to make a social and political difference (Friedman, 2013). Instead, he became an editor of a Jewish newspaper.

The decisions taken by Fromm in those early years signaled the type of intellectual that he wanted to be. Firstly, he was not afraid to take an unpopular stance, as he moved beyond the Judaism and later the Zionism of his family. Secondly, in the Marxist vein that increasingly came to influence him, Fromm did not want to simply interpret the world, but aspired to change it. Realizing that such ambitions might be possible by reaching a broader public, he aspired to be what we now call a public intellectual.

His public intellectual career, however, would have to wait. After graduating and then quitting the Jewish newspaper, Fromm became a trained psychoanalyst working in Berlin. In that period he resumed his academic and theoretical work when he accepted the invitation from Max Horkheimer in 1929

to become a member of *Institut für Sozialforschung* (the Frankfurt Institute for Social Research), a network of interdisciplinary scholars we now know of as the Frankfurt School. Fromm was director of social psychology and worked with the critical theorists as a researcher (Friedman, 2013: 26). The rise of National Socialism and growing anti-Semitism pushed Fromm to leave Germany first to Switzerland then to New York, where he worked with the now exiled immigrant members of the Frankfurt School (Wheatland, 2009) at Columbia University. The Frankfurt School was brought to Columbia largely due to the efforts of the sociology department, particularly Robert Lynd, because they were interested in Fromm's research on the working class in Weimar Germany (Wheatland, 2009).

Fromm's work in the institute dealt with family, religion, anti-Semitism, the class-biased punitive justice system, scapegoating, and much more (Friedman, 2013: 34). Fromm participated in and codesigned collaborative projects, wrote for the critical theorist's journal, and received a significant wage (Friedman, 2013: 31). During the 1930s, Fromm had conducted a major empirical study of the social psychology of Weimar German workers, work that created the concept of 'authoritarian character.' Fromm's position in the Frankfurt School evolved together with changing social and personal life circumstances. When they started cooperation, Fromm had just finished his psychoanalytic training and could maintain a working relationship with Horkheimer, who was influenced by Freudian orthodoxy. With time, however, this cooperation would unravel. Fromm started to distance himself theoretically from the Frankfurt School at the time when he started a relationship, in the US, with Freudian revisionist Karen Horney. As Lawrence Friedman argued, Fromm adapted to life in the U.S. rather quickly. He was the only member of the Frankfurt School who quickly moved from 'proficiency to mastery of English' and started publishing in this language (2013: 78). Additionally, Fromm put in extra effort to become familiar with and interested in American popular culture, and dabbled with commenting on relevant American matters, activities that Adorno criticized. Soon, he joined a network of thinkers called the 'Culture and Personality' movement with his friends Edward Sapir, Ruth Benedict, and Margaret Mead (Friedman, 2013: 59) and began attending weekly meetings of the Zodiac Group which consisted of artists, scholars, and poets exchanging ideas (Greenberg and Mitchell, 1983). Thus, Fromm's social networks went beyond Horkheimer's circle to include relationships with other social and political scientists from Columbia University. Finally, Fromm acquired independence from Frankfurt School in yet another way – by being a successful psychoanalyst, with a stable source of income. All this intensified the growing conflict between Fromm and the members of Frankfurt School. Both Horkheimer and Adorno were suspicious of Fromm's ability and willingness to connect to American scholars and political and cultural trends (Wiggerhaus, 1986). Over time, they would respond by trying to diminish his role in the critical school of thought, helping render him a 'forgotten intellectual' (McLaughlin, 1998, 1999).

Fromm always rejected orthodoxies, and he did not hesitate to publish a series of critiques of psychoanalytic theory, throughout the 1930s (Burston, 1991), as his emerging ideas represent a significant break from Freudian orthodoxy. For Horkheimer and his colleagues, Fromm's work deviated far too much from their theoretical agenda and eventually they would pressure him to leave (Friedman, 2013: 37). Conflicts over Fromm's unorthodox reading of Freud and Marx, financial matters (Friedman, 2013: 57), and disagreements over methodological and practical matters relating to the proposed publication of his study of the working class in Weimar Germany led to him leave Horkheimer's group in 1939 (Burston, 1991; Wiggerhaus, 1986). Fromm's research from this period, however, created the basis for *Escape from Freedom* (1941). Published with a commercial press and written in engaging nonacademic prose, *Escape from Freedom* argued that popular psychological explanations overemphasized Hitler's pathological personality and the 'madness' of the sociopolitical movement supporting him. Furthermore, Fromm opposed Marxist deterministic interpretations suggesting that Nazis simply served the interest of authoritarian German capitalists. Instead, Fromm offered a more complex sociological explanation of Nazism, linking this movement with anxieties arising out of rapid social changes brought about by modernity (McLaughlin, 1996). He suggested that humiliation experienced by Germany after World War I and the subsequent economic crisis undermined the legitimacy of its democratic institutions, making its citizens more anxious. The millions of Germans were seduced by Hitler's 'evangelism of self-annihilation' (Fromm, 1969[1941]: 259) that was offering a way to reverse the effects of cultural and economic collapse. One path to escape from freedom, in Fromm's view, was offered through following obediently a leader and his racist, nationalistic, and militaristic Nazi Party (Fromm, 1969[1941]: 235). As the noted political theorist and historian of psychoanalysis Paul Roazen observed, the publication of this book "was a notable moment in intellectual history" (Roazen, 1977). Not only was it enthusiastically reviewed in elite newspapers and magazines (McLaughlin, 1996) but it also influenced generations of social scientists such as Robert K. Merton's graduate students at Columbia University.

Ironically, the success of *Escape from Freedom* helped erase from our historical memory Fromm's influence on Horkheimer's circle. Fromm became known as a theorist of freedom not authoritarianism (Rickert, 1983), and gradually came to be ignored by contemporary critical theorists who accepted Marcuse and Adorno's account of the conflict within the Frankfurt School circle (McLaughlin, 1999). This erasure of Fromm from this history is unjustified, since his study of the character of Weimar German workers laid the foundation for the concept of 'authoritarian personality' that Theodor Adorno used to write *The Authoritarian Personality*, making authoritarianism almost a brand-name concept for the Frankfurt School (McLaughlin, 1998; Brunner, 1994). Fromm's work underpinned the development of the authoritarian personality tradition, which allowed social scientists to combine psychological explanations of scapegoating occurring in political life with an empirical 'F' scale measure of the level of authoritarianism. The involvement of Fromm in developing an earlier version of the 'F' scale was never adequately recognized until the publication of the manuscript of *The Working Class in Weimar Germany* (Bonns, 1984).

The Sociology of Race and Racism

The concept of authoritarian character introduced in *Escape from Freedom* was relevant for the development of literature on xenophobia and prejudice in the early twentieth century (Chancer, 1991). Fromm's studies of prejudice concentrated on historical circumstances conducive to its emergence, but also attempted to reveal more universal aspects of oppression. He identified a mechanism in which the dominating authoritarian person feels freer, more secure, and powerful knowing that there is someone whom they can or they have already managed to dominate. In this sense, the term 'social character' coined by Fromm to describe common traits of people belonging to the same group can be seen as providing means for the expression of group narcissism (superior 'us' as opposed to inferior 'them') and of nonegalitarian or authoritarian personality that feed unconscious racism (Fromm, 1964), key elements in contemporary scholarship. In short, Fromm's contribution to the study of prejudice and racism comes down to highlighting social psychological aspects of these phenomena.

Revisiting Fromm's contributions (especially the concept of 'social character') seems fruitful in the context of racism studies' shift of their scope from explicit conscious racism to automatic, unconscious racism (see Wheeler and Fiske, 2006[I1]). Few race scholars implied that subscribing to egalitarian values that bypass the cognitive process of forming stereotypes can also inhibit the development of unconscious biased, prejudiced, or racist attitudes (Pearson et al., 2009). Pearson et al. tested this contention by utilizing Fromm's Marxist-influenced concept of the 'marketing character,' a personality interested in maintaining economic differences among people. Pearson et al. concluded that people demonstrating traits of 'marketing character' are more prone to be racially prejudiced than those believing in an equal distribution of material resources. Fromm's use of Freudian insights into unconscious drives and emotions combined with Marxist and Weberian sociological perspectives on class and status provides productive intellectual resources for contemporary prejudice and race scholars.

The strengths as well as some of the limitations of Fromm's theorizing of race emerged both from his positioning between various networks and from his personal life. The combination of Fromm's socialist politics with his prophetic Jewish ethical thinking was creatively translated into his works (e.g., *The Heart of Man* or *The Anatomy of Human Destructiveness*) which, while discussing more ethical concepts such as the human roots of evil and destructiveness, criticized at the same time racism, ethnocentrism, and nationalist chauvinism (Fromm, 1964, 1973). On a more personal level, a large part of Fromm's energies in the 1930s were spent on trying to rescue Jewish family and friends from Nazi prosecution (Friedman, 2013). But also, after his break up with German psychoanalyst Karen Horney, he started seeing Katherine Dunham – a talented African-American dancer, choreographer, graduate of social anthropology, and researcher at the University of Chicago (Friedman, 2013: 91). This rare interracial relationship in 1930s America, as Lawrence Friedman argued, opened Fromm's eyes to discrimination and constraints that African-Americans experienced, even though, like many German émigré scholars, Fromm never fully understood the nuances of American racial politics. His connection to Dunham, his involvement in the American socialist party in the 1950s and early 1960s, and his intellectual engagement with the American pragmatism of John Dewey (a foreign territory to Marcuse and Adorno) meant that *Escape from Freedom*, which he wrote while dating Dunham, (1941) and his later book *The Sane Society* (1955) contained an emotionally compelling defense of antiracist universalism, even though he failed to theorize racism and anti-Semitism adequately. This universalism led him to gender theories to which we now turn.

Gender, Freud, and Psychoanalytic Feminist Sociology

Fromm's contributions to theories of gender are considerable yet controversial. Fromm's role in transforming of Freud's patriarchal psychological theory into the object relation psychology, self-psychology and feminist psychoanalytic sociology was obvious from the 1930s till today. By synthesizing Marx's and Freud's insights into the dynamics of character, emotions, and the unconscious, in the context of an empirical sociology, Fromm arrived at completely different conclusions than Freud about the role of the mother in the life of child. Freud's views of woman as essentially a castrated man were replaced by a theory that saw the mother as a powerful figure in child's life and their relationship as the strongest connection humans can have.

Another element of Freud's theory that Fromm questioned was the assumption of the universal character of femininity and masculinity; Fromm's revision of psychoanalysis attempted to show the socially constructed nature of these categories (Davis, 2003). This theoretically based criticism was later built on by sociologist Nancy Chodorow, who used empirical clinical data to develop the critique of the adequacy of Freudian theories of Oedipus complex and penis envy (1978). The revision of Freudian theory that Fromm offered (Burston, 1991; Rasmussen and Salhani, 2008) made him one of the most visible, articulate, and effective critics of psychoanalytic orthodoxy in the 1940s through the early 1960s.

Fromm's contribution to the emergence of feminist psychoanalysis can, once more, be explained by his personal life and sociological position on the optimal margins of psychoanalysis. Fromm's ideas can be recognized as contributing to the development of object relation theory (Chodorow, 1989; Greenberg and Mitchell, 1983; Chodorow, 1978: 50). Fromm's sociological vision insisted on seeing each patient's individual relational history as a sociologically shaped trajectory, which indirectly led to a crystallization of object relations theory in psychoanalysis and in social science more generally.

Fromm's ties and relationships with several remarkable women impacted the direction he took in his work (Davis, 2003). These women were either his mentors, like his first wife Frieda Fromm-Reichmann, or his intellectual partners who helped to broaden his horizons, like Katherine Dunham or Karen Horney, or his colleagues or fellows, in this case, female intellectuals, like Margaret Mead, with whom he worked within various intellectual circles (Burston, 1991; Rasmussen and Salhani, 2008).

Fromm's fascination with psychoanalysis started at the university, but was accelerated by his encounter with his

therapist and then first wife Frieda Fromm-Reichmann (Friedman, 2013: 21). Thus, in his late 20s, Fromm underwent psychoanalytic training and went on to work successfully as a clinician for 44 years (Ortmeyer, 1998; Burston, 1991). Frieda at the time helped him transition from Jewish Orthodoxy and Freudian orthodoxy as he moved beyond both. Fromm-Reichmann's ideas shaped Fromm's emerging intellectual agenda in the 1920s and certainly she helped him establish himself professionally. She was not, however, the last woman to have a transformative and generative influence on his life and ideas.

Protofeminist psychoanalytic theorist (Westkott, 1986) and cultural critic Karen Horney also had a pivotal influence on Fromm's revised psychoanalysis and on his career as a public intellectual. Fromm learned a lot from her while they dated in the United States in the 1930s. Horney's writing that made her books best sellers was arguably the inspiration for Fromm's strategy of producing easily accessible works, such as *Escape from Freedom* (1941), *The Sane Society* (1955), *To Have or to Be?* (1976), that could be published by commercial presses. But what is more important, Fromm owed Horney for her insights into the 'womb' envy theory that she offered as an alternative to the Freudian patriarchal concept of 'penis envy.'

Fromm's success as the major critique of Freudian orthodoxy in the 1940s and 1950s had much to do with his position on the optimal margins of the field and his connection to various collaborative circles and intellectual social movements. Fromm and Horney shared a critique of Freudian orthodoxy, but his connection to the Frankfurt School network made him more independent than Horney, who was essentially a Freudian psychoanalyst who wrote books on the side. As a consequence, Fromm's critiques of Freudian orthodoxy were more direct and perhaps harsher. However, after his relationship with Horney dissolved, she limited his power in Association for the Advancement of Psychoanalysis (APA), which was dependant on the financial support from institutions working in the Freudian orthodox tradition (Friedman, 2013). In short, allowing Fromm a central position in APA could jeopardize Horney's professional project (Friedman, 2013). As a consequence, Fromm was assigned to a place ever more on the fringes of networks among Northern American Freudian orthodox psychoanalysts than he had occupied in the early 1930s.

Fromm's personal life took two big turns when the poor health of his second wife (Henny Gurland) pushed the couple to move to Mexico in 1950 (Friedman, 2013: 139), where, after a few years of fighting depression and chronic pain, Henny committed suicide. A year later life offered a last romantic surprise when Fromm met his third wife (Annis Freeman) and ended up staying in Mexico. His new companion was fascinated with Buddhism, meditation, and international politics resulting (Friedman, 2013: 170) in a happy home in Mexico and their remaining married for 27 years until his death in 1980. The deep affection between Erich and Annis found expression in Fromm's most popular book *The Art of Loving* (1956) as well as in a general increase in Fromm's productivity. Between 1955 and 1968, when he had an almost fatal heart attack, Fromm published many books, including *The Sane Society* (1955), *Marx's Concept of Man* (1961), *May Man Prevail?* (1962), *Beyond the Chains of Illusion* (1962), *The Heart of Man* (1964), and *The Revolution of Hope* (1968).

Over these years in Mexico, Fromm founded the Mexican Institute of Psychoanalysis, trained early generations of psychoanalysts, and became a central figure in Latin American psychoanalysis. Once again, Fromm's marginality in one place was optimal in another because his connections transcended various networks. The freedom that Fromm gained by distancing himself from the New York psychoanalytic establishment combined with the importance of the mother in Catholic Latin American culture, reinforced his revisionist tendencies. Even though, as sociologist Lynn Chancer argued, Fromm's work anticipated new trends in psychoanalytic sociology and emphasized pioneering feminist and existentialist themes beyond libido theory (1992), his Mexican exile meant that he was on the margins and not in the center of transformations that psychoanalysis was undergoing; Fromm's pioneering role in the development of psychoanalytic sociology hardly made him a feminist in contemporary terms. Fromm's writing, filled with exaggerated male and female difference and often marred by the homophobia deeply inscribed with much psychoanalytic theory, limits the usefulness of his gender analysis without significant reformulation. Ironically, nonetheless, the ways that Fromm drew on and developed critiques of orthodox Freudian theory from his very unique marginalized position helped create contemporary psychoanalytic feminism – though also ensuring that Fromm himself would be marginalized in psychoanalysis.

Fromm's critique of Freud had its foundations in the largely ignored works of Bachofen, a nineteenth-century Swiss aristocrat, who anticipated some of Freud's views but whose work analyzing ancient myths suggested that the matriarchal social structure preceded the patriarchal one. Bachofen's *Mother Right – Das Mutterrecht* (1861) inspired Fromm to write an article on matriarchy back in 1934 (Burston, 1991; Fromm, 1934; Fromm and Maccoby, 1970; Ortmeyer, 1998). Later, in *The Anatomy of Human Destructiveness*, Fromm extensively discussed the excavations at Çatal Hüyük (in present day Turkey) and the existence of a Neolithic culture characterized by feminine values (Bacciagaluppi, 2001; Fromm, 1973), making the argument that matriarchal social organization could be seen as a legitimate alternative to patriarchy. Various feminist thinkers, including Mary Daly and Riane Eiasler, would build from Fromm's discussion of matriarchy (Bacciagaluppi, 2001). Fromm thus contributed to the emergence of a set of ideas within radical feminist circles in the 1970s.

Fromm's critique of Freudian orthodoxy did not flow simply from his reading of Bachofen but also emerged from many discussions in the 1930s with the New York City–based Zodiac club, an informal social circle of thinkers that existed on the margins of psychoanalysis and anthropology and psychiatry. This group consisted of such brilliant intellectuals as Horney, Margaret Mead, Ruth Benedict, and American psychiatrist Harry Stack Sullivan. The mental health professionals in the group founded the White Institute in Washington DC, a nonorthodox Freudian center of innovative theorizing, where the position of the director of clinical training was given to Fromm. This new institutional affiliation allowed him to even more openly reject drive theory, since his colleagues were also Freudian revisionists, social psychologists, or neo-Freudians (Greenberg and Mitchell, 1983).

Fromm's revisionist ideas, forged in marginal networks but institutionalized into a revisionist training institute, went on to contribute greatly to the development of object relation theory (Chodorow, 1989; Greenberg and Mitchell, 1983). A version of Fromm's theory of social character and object relations theory is applied to the phenomenon of mothering in *The Reproduction of Mothering* by Nancy Chodorow and developed further in her extensive writings. Chodorow's sociological project was rooted in an attempt to understand how people create a social environment that exclusively recruits mothers as the only ones doing the mothering or caretaking (1978). Chodorow approached this theoretical task by linking psychoanalysis with a feminist sociology of gender while paying attention to finding an empirical basis in clinical evidence, an approach pioneered by Fromm in opposition to the purely philosophical Freud defended by Adorno and Marcuse (Chodorow, 1978: 74; Rickert, 1983).

Fromm did not receive an adequate credit for his role in the development of the rich object relations tradition in psychoanalysis for a variety of reasons. Bachofen's work is problematic in light of contemporary archeological research, and thus Fromm's use of his ideas hurts his scholarly reputation. Fromm's followers among radical feminist circles were highly controversial themselves in academic and intellectual circles, and they were not likely to become followers of Fromm given some of his problematic writings on gender. The personal and political-intellectual differences between the various members of the Zodiac club, and their very different career trajectories, ensured that no coherent schools of thought emerged out of various neo-Freudian networks (McLaughlin, 1998). And some of Fromm's personal sexual politics leave much to be desired (Friedman, 2013).

Public Intellectual and Public Sociologist

Over and above the theoretical contributions Fromm made to psychoanalysis and sociology, his legacy is worth remembering and building on because of his role in creating the very genres of modern 'public intellectual' and 'public sociologist' that have become widely debated in recent decades (Jacoby, 1987; Burawoy, 2005). Even though citations of Fromm in sociology journals declined dramatically from the height of his influence in the 1940s and 1950s, he had an unacknowledged influence on major public sociologists.

Fromm's clear way of communicating with readers was emulated by Fromm's psychoanalytic patient and close friend, Harvard professor, David Riesman, whose *The Lonely Crowd* published in 1950 became the best-selling sociological book of all time (McLaughlin, 2001b). Fromm's *Escape from Freedom* and *Man for Himself* (1947) were a major inspiration for the analysis of 'inner-' and 'other-' directed social characters outlined in Riesman's sociological classic (McLaughlin, 2001b). In many ways Riesman's work improved on Fromm's by providing a political balance, a scholarly style, and a liberal philosophical commitment while avoiding the excessively prophetic tone of some of Fromm's socialist polemic and moralistic writings (Maccoby, 1995). But Fromm's influence on Riesman is significant, and Riesman was arguably the major public sociologist of the twentieth century, at least in America.

There is also considerable similarity between the style and the content of the work of Erich Fromm and Zygmunt Bauman (Davis, 2008). Bauman, a Polish sociologist, now an émigré UK professor at Leeds University, known for theorizing 'liquid modernity,' shares with Fromm roots in humanistic Marxism. Both thinkers discussed the importance of capitalist ideology; both described life in late modernity as marked by individuation, alienation, an emergence of freedom that becomes an 'unbearable psychological burden,' and the disappearance of people's ability to love (Catlaw, 2009); both stressed the negative consequences of obsessive-compulsive consumption and market-oriented personalities (Ziółkowski, 1998). Despite numerous differences (Bauman's multiple worlds in liquid modernity as opposed to Fromm's commoditized and internalized world (Smith, 1999; Best, 2013)), the similarities between their works are undeniable. And if Riesman was the dominant American public sociology in the 1950s, Bauman has been a very influential public sociologist in Europe from the 1990s through the first decade of the twenty-first century.

Fromm's legacy as a public intellectual and public sociologist should not be ignored. As Lawrence Friedman has documented, Fromm played a direct role in President Kennedy's disarmament policy (Friedman, 2013); Fromm was a devoted antiwar activist whose condemnation of the Vietnam War and American imperialistic ambitions was articulated in work and in his testimony before the U.S. Congress, and he was a philanthropist who gave enormous amounts of money to Amnesty International (Friedman, 2013). In short, being faithful to his humanistic views, Fromm considered the survival of the human race as a way to "realize … human solidarity" (Fromm in Wilde, 2000). Fromm's politically engaged work paved the way for other sociological books to appear on the shelves at homes of millions of readers, including policy makers, around the world.

Conclusion

Erich Fromm's legacy can be summarized in two ways. Firstly, his ideas shaped scholarship on the sociology of authoritarianism, race and racism, gender, and historical social psychology. Secondly, through his life and work as a public intellectual and public sociologist he created a template for future generations of engaged intellectuals. Fromm's work had an enormous influence on twentieth-century social science and his legacy remains useful today.

The revival of interest in his theories, activism, and engagement in public affairs cuts across all disciplines and genres of social science writing. His theory of love is being used by education scholars (Wesh in Hay, 2011; Fleming, 2012). Furthermore, Fromm's work has inspired criminologists (Anderson, 1999; Lowy, 2013), peace scholars (Housden, 2013), political theorists (Durkin, 2014), and academics theorizing social work (Rasmussen and Salhani, 2008; Houston, 2010). Political theorists have returned to Fromm's radical humanism, suggesting new ways forward for his political philosophy, perhaps now framed in less prophetic and moralistic terms (Wilde, 2000). Critical theorists seem far less interested in refighting sectarian intellectual battles from the 1930s, as the Frankfurt School retools itself to engage empirical

social science anew with insights that we might place more modestly now in a tradition that Burawoy calls 'critical sociology' (2005). The dominance in sociological debates of Bourdieu's reflexive sociology and concept of habitus calls for a revisiting of Fromm's theoretically complementary concept of social character (Cheliotos, 2011a). And after decades of the dominance of rational choice theory in the social sciences, there is much space to reinsert Fromm's psychoanalytic revision of emotions, albeit now more centrally attuned to gender and race. We live in a time where authoritarianism and violence are breaking out everywhere, and Fromm's early ecologically oriented vision is more relevant than ever (Fromm, 1976). Fromm's legacy is likely to be built on creatively in the twenty-first century in various ways, in the optimal margins of contemporary social science, as was the case in the 1930s, 1940s, 1950s, and 1960s.

Frontiers in History

Alfred J Rieber, The Central European University, Budapest, Hungary

Abstract

Studies on the frontier in history have undergone important methodological and thematic changes over the past two decades, becoming more interdisciplinary and reinterpreting the main features of frontiers in the fields of North American, Russian, Ottoman, and Chinese history. This article seeks to illustrate the themes common to all these fields and to examine separately each one emphasizing the revisionist interpretations and presenting a comparative dimension where appropriate.

The Changing Context

Three shifts in perception over the past two decades have stimulated new conceptual and interpretive approaches to the study of frontiers in history. The first was driven by the spatial turn, the second by changes in global geopolitics, and the third by the expansion of scholarship in non-European areas of specialization. The spatial turn reflected the qualitative and quantitative increase in the borrowing and adaptation of the social sciences by historians, as well as a greater awareness of historical processes in fields such as geography and anthropology (Osterhammel, 1998). The interaction has not always been an equal exchange. Witness the terminological and conceptual difference that has emerged between frontiers and borders. Although the distinction between the two is often blurred in the literature, historians prefer the former and geographers, sociologists, and anthropologists prefer the latter. In a recent compendium on borders, only one of the 40 contributors was a historian (Wastl-Walter, 2010). For most historians, a frontier signifies a shifting and contested intermediate zone of conflict and exchange on the periphery of a territorial core with an ethnically mixed population, exposed to internal and external change over a long duration and engaged in mutual interactions with the institutions and cultural practices of the core. Border scholars share some of these views, but they treat borders as a clearly defined line separating organized spatial units while reserving the concept of borderland for similar ethnocultural areas on opposite sides of state boundaries. Their consideration of borders tends to be chronologically limited to the twentieth and twenty-first centuries, referring to earlier periods by analyzing collective memory. An attempt to reconcile these differences argues that "a basic distinction between frontiers which are zones of settlement and frontiers which constitute political barriers is apparent in most frontier historiography" (Power and Standen, 1999). The second impetus to the growing number of frontier studies came with the dissolution of the Soviet Union, the redrawing of Europe's borders, the deterritorializing effects of globalism, and the reterritorializing of state boundaries after 9/11, all factors in the displacement of familiar spaces. The third impetus came from regional specialists in the historical profession. They have made more extensive use of the comparative approach and revived interest in the role of frontiers in the processes of state formation and ethnic identification. The proliferation of these studies, challenging established theories, has been particularly significant in North American, Ottoman, Russian, and Chinese histories.

Among the most recurrent themes in recent histories of frontiers four stand out: the tension between hybridity, transfer, and exchange on the one hand and military, sanitary, and cultural barriers on the other hand; the reciprocal influences of the frontier (periphery) and the centers of power (core) on constructing and deconstructing imperial state systems; the multiplicity of both external and internal frontiers; and symbolic or discursive as opposed to geopolitical frontiers.

Frontiers and the Social Sciences

Anthropologists came later than historians to frontier studies but then arrived in considerable force. In the 1950s, they began to engage in extensive field work on the margins of sedentary and nomadic societies. Their insights were rapidly absorbed by historians who had already been seriously exploring frontiers for over half a century. Geographers based in local history and influenced by cultural studies began to redefine the ideas of space and frontiers in terms of linguistic and social contexts (Godlewka and Smith, 1994; Driver and Samuel, 1995; and Lewis and Wigen, 2000). The so-called textual approach appealed strongly to non-European postcolonialist scholars who coined the term 'textualizing the world,' meaning the mental construction of the globe and its discursive subdivisions to fit the European vision (Spivak, 1990). Both sociologists and anthropologists explored ways in which ethnic identity and concepts of citizenship corresponded to the drawing of territorial boundaries (Brubaker, 1992). Semioticians perceived frontiers as 'zones of cultural bilingualism' (Lotman and Uspenskii, 1984, 3–15). Despite changing contexts and multidisciplinary approaches, most American and comparative historians of the frontier keep returning to the original work of Frederick Jackson Turner, if only to refute him. Only a few comparative studies have sought to develop systematic frameworks for analysis that have not taken the Turner thesis as a point of departure or a foil for revision (Rieber, 2004).

The Turner Thesis and Its Critics

It is well over 100 years ago that Frederick Jackson Turner published his now world famous influential essay on the frontier in

American history (Turner, 1920, 1893). For American historiography, the great explanatory power of his vision resided in its claim to explain the uniqueness of American civilization. Since then his concept of the frontier has undergone extensive revision, which in the middle years of the twentieth century reached the point where a body of scholarship banished the word frontiers from historical discourse. However, the complexity of his approach guaranteed its longevity and survival even as a foil. Multidisciplinary in spirit if not in word, he combined elements of economic thought, geography, social history, and the history of ideas even though he was not always consistent in establishing the relationship among them. His brilliant essays added up to something less than a full-blown theory and left the way open for multiple interpretations, extensive revision, and critical refutation. Like many great theses in historiography, its importance lies as much in the literature it generated as its original propositions. Given the large number of American historians and the academic culture of methodological restlessness in the United States, it is not surprising that the main changes in conceptualizing the history of frontiers has been dominated by revisions of Turner's original thesis (Adelman and Aron, 1999).

Revisionism in the United States

In American historiography, the revisions and reformulations of the Turner thesis radiate around two conceptual poles: new methodologies, particularly anthropology and environmental studies, and fresh interpretive perspectives, reflecting the shifting concerns of a society in search of itself. The task of charting the currents of the debate has itself become a minor cottage industry (Nash, 1991). Turner's frontier as an advancing line of settlement has given way, in the work of the regionalists, to a multiplicity of locations. However, Turner's tendency to conflate the frontier as a line and 'the Great West' as a region continues to be a source of confusion. There has also been a trend in American historiography away from spatial to cultural definitions of the frontier, although Turner himself made room for both place and process in his own work.

Turner's concept of the frontier as dividing 'savagery from civilization' or alternatively as a forward movement into 'empty lands' was challenged, under the influence of anthropologists, by the idea of the frontier as a 'middle ground' of intermingling of Native Americans and European settlers engaged in a variety of cultural and commercial 'frontier exchanges' (White, 1991). Turner's vision of the West as an environment that bred rugged individualism and privileged self-reliance also encountered criticism from historians and sociologists who gave equal prominence to social collectivities. Critics also uncovered a darker side of the frontiersman in the legacy of a gun culture and the persistent cult of violence (Graham and Gurr, 1969).

Environmentalist historians exploded Turner's arcadian picture of natural harmony on the frontier by exposing the depredations, manipulations, and 'species shifting' impact of the Western advance (Cronon et al., 1992). Turner's insistence on the defining role of the frontier experience in building American democratic institutions failed to account for the contributions of urban life and the antecedent values that the pioneers brought with them from the eastern seaboard or Europe. At one end of the historiographical spectrum, Turner's thesis lies in ruins. At the other end, attempts have been made to synthesize the newer ideas on race, class and gender, and region or to revive older ideas of conflict and conquest in order to rescue once again the place of the frontier in American history (Nobles, 1997; Wooster, 2009). However, a multicultural interpretation of the frontier requires a radical reversal of the original myth. Not only does the advancing frontier signify the virtual extermination of the Native American population, but it also takes on a plurality of meanings for other ethnic groups. Their frontiers are formed and advanced after the official closing of the frontier in 1892 that caused Turner to bemoan the loss of what he regarded as a unique part of American life. In the twentieth century, the territorial and social mobility of the Hispanic-, Afro-, and Asian-Americans constituted in their eyes a formative experience that *mutatis mutandis* enthralled the pioneers of the nineteenth century (Takaki, 1993).

The commercialization of American history found the perfect vehicle in the myth of the frontier. Frontier images penetrated the world of mass entertainment, advertising, and journalism. The 'Western' film as a genre enjoys enduring popularity because it is able to incorporate changes in social values while retaining the centrality of the myth. New social and environmental concerns have left deep marks on the Turnerian stereotypes of the Old West. In films and television, the heroic cowboy in the white hat, the intrepid pioneer fighting off the Indians, and the US cavalry riding to the rescue at the last moment have become more ambiguous figures. Black cowboys and troopers, environmentally sensitive Native Americans, and even women gunslingers have challenged the dominant white male image.

The official closure of the land frontier in 1892 did not deter Turner from speculating on the further advance of an American oceanic frontier that would extend to the shores of the Asian mainland. In this quest for new frontiers to conquer, he was joined by several other influential American publicists who were even more specific in their advocacy of an expansionist American empire overseas. Their ideas fit in well with a cluster of ideas in the 1890s that merged geopolitics, social Darwinism, the Anglo-American mission or Manifest Destiny, and the Open Door Policy, all with strong anti-Russian implications. They influenced the world view of Woodrow Wilson and later politicians. The use of the word frontiers became so attenuated as to lose much of its original meaning. Surfacing in different contexts, it took its most politicized form in countering the perceived threat of postwar Soviet expansion of its frontiers.

Revisionism in the British Commonwealth

The Turner thesis had implications beyond American history insofar as he established the frontier as a historical problem. Paradoxically, it also became a reference point for scholars seeking to adopt or refute its implications for a whole series of different societies that shared, however, similar features of a frontier of moving settlements. The applicability of the Turner thesis to other British colonial experiences leading to the establishment of white settler communities has given rise to discussion over the degree to which the American frontier was unique. There were certain common features of the frontier experience and its incorporation into the national narrative that were shared

by Canada, Australia, and New Zealand, even to a lesser extent South Africa: the belief in a manifest destiny, the struggle to tame the wilderness, the origins of a democratic society. Some comparative studies of the frontier experience in Canada, Australia, and New Zealand with Turnerian overtones argue that despite superficial similarities with the United States, geographical factors and the prolonged tutorship of the metropolitan center in Great Britain discouraged the mythology of frontier exceptionalism. In Canada, there were close parallels between the farming frontiers in Ontario and Saskatchewan and in North Dakota and Montana. However, the expansion toward west was delayed by the physical barrier of the Canadian Shield. When it came it was promoted by Royal Governors who established a national police (the Royal Mounties) before mass immigration and who negotiated settlements with the Blackfoot tribes thus heading off the local violence and white–Native American wars that characterized the American west. To an even greater extent, the geography of Australia, dominated by a vast arid region in the center, 'a hinterland but no heartland,' relegated the bulk of the population to the cities on the east and south coast while royal land policy did not favor the small farmer in competition with the large sheep ranges. Even here there are regional similarities between the semiarid fringes of California and Victoria. Australia had its frontier folk hero in the form of the bushranger, although he was connected to the convict life rather than the freebooter born in an open society.

Some Canadian historians interpreted the differences from the United States in order to propose their own myth of a 'northern vision' to set against Turner's 'West' as a foundation block of Canadian national character. The thesis drew heavily on British and continental writers and social Darwinists who romanticized northern peoples as hardy, industrious, and democratic. They combined this version of geographical transcendence with the 'staple thesis' that tied Canada's economy to the global metropolitan community through the production of raw materials, thus departing from the American concept that separated its West from the Old World. However, the combination of the northern vision and the stables thesis failed to generate the same mythic power as the American frontier (Katerberg, 2003).

Recent research has forced a reevaluation of Turner's preoccupation with the experience of Anglophone settlers and a reorientation of his East to West movement by portraying the role played by French merchant families along the Creole corridor stretching from the Great Lakes through the Mississippi Valley to the Gulf of Mexico. Instead of Turner's frontiersman as a rugged individual, the legendary mountain man, fur trader, and Indian hunter, an alternative portrait emerges of an urban, cosmopolitan, 'bourgeois' who negotiated rather than drove the Indians out of their lands even after the French lost Canada (Gitlin, 2010). Like the Hispanic frontier of the southwest United States, the Creole frontier adds to the complexity and multiplicity of American frontiers.

Russian Frontiers

As an interpretive point of departure, historians of the Russian frontiers have been most strongly influenced by the frontier thesis proposed by Turner and the subsequent revisions. For the classic Russian historians S.M. Solov'ev, V.O. Kliuchevsky, and M.K. Liubavskii, the latitudinal zones of forest and steppe provided the natural setting, facilitating the advance of the frontier through colonization and conquest. Although they did not develop a frontier thesis, they drew on many of the same intellectual foundations as Turner (Bassin, 1993). By contrast, however, their interpretations emphasized the negative effects: The draining of resources from the center, the unfavorable conditions of climate and soil, and the threat of nomadic incursions. Historians in the early Soviet period added to this somber list the exploitation of conquered people, exemplified by M.N. Pokrovskii's well-known image of the empire as a 'prison of nations.' A strong reversal set in only after World War II when the new state school of Soviet historians extolled the peasant colonizer as a heroic figure and revived the prerevolutionary term *sblizhenie* (drawing together in friendship) to signify the civilizing mission of the Russian people. A third turn has been taken only recently by the emerging regional (Siberian) school of historians, who, in readjusting their focus to the specific features and values of societies on the periphery at odds with those of the center, have nonetheless also acknowledged a debt to Turner. In the most recent general reassessment, Boris Mironov has interpreted colonization as primarily a demographic phenomena. In his view, Russia's territorial expansion was the optimal solution for a society burdened by over population, poor in capital but rich in human resources and land available for colonization. In making comparisons with the United States, he used the Turner thesis and its critics to emphasize the differences and the greater benefits brought to American civilization by frontier expansion (Mironov, 1999; Mironov and Ekloff, 2000).

Since the 1980s, a new generation of American and British specialists in Russian colonization has been incorporating fresh insights borrowed in part from revisionist American historians of the western United States and in part from anthropology and cultural studies while mostly avoiding direct comparisons with the American experience. The emphasis has shifted from conquest and resistance on the frontier to cultural interaction, an interrogation of geographical visions, multiple locus, and images of frontier utopias. The multiplicity of Russia's frontiers has inspired scholars to propose functional categories such as military, extractive, and colonized (Kappeler, 2003). The rejection of Turner's idea of 'empty lands' and dismissal of the Native American experience as factors in forming the frontier have their parallel in the restoration of the steppe people in the history of the Russian frontier. The view of the frontier as a locus of exchange and hybridity has eroded the traditional emphasis on conflict and hostility (Breyfogle, 2005). White's concept of 'the middle ground' has been employed to analyze the dynamic interaction between the state and the migrating peasants in settling the frontier (Moon, 1997).

The closing of the Russian frontiers was no sooner completed with the delimitation of the Afghan boundary in 1885 than the Bolshevik Revolution burst them open again. The subsequent Civil War confronted the early Bolshevik leaders with two irreconcilable problems. Externally, they were committed to abolishing frontiers, but practical necessity dictated establishing new interstate boundaries on ethnically

mixed frontiers. Internally, they were committed to creating boundaries for newly created national units on equally fluid frontiers. The attempt to reconcile these inherent contradictions ultimately failed. The external expansion of the frontiers through the medium of popular democracies in a protective belt around the Soviet homeland began to break down almost immediately after World War II with the Yugoslav case and was then repeatedly challenged by revolts in Hungary and Czechoslovakia; disaffection in Poland; and defections by Albania, Romania, and China. The internal consolidation of national Soviet republics spurred centrifugal forces that together with the external centripetal forces destroyed the entire system, opening up new, multiple, and contested frontiers in the twenty-first century.

Chinese Frontiers

The pioneering figure in Chinese frontier studies was Owen Lattimore. His central thesis was to establish that frontiers as distinct from boundaries were the margins of socioeconomic systems defined by their 'optimal limit of growth.' He was the first to stress the dynamics of frontier exchange in Chinese nomadic relations. The interaction of the nomadic and sedentary societies produced a unique form of frontier culture, which he called 'frontier feudalism.' The key to the system was the shift from a clan to a territorial-based organization of the nomads on the margins. This was the result of a Chinese policy of creating a patron–client relationship with the frontier nomads. While admitting that Frederick Jackson Turner was an acute observer, Lattimore added, "what he saw so clearly he saw standing on his head. In large measure, when he thought he saw what the frontier had done to society, he was really seeing what society did to the frontier" (Lattimore, 1962).

For Lattimore, Manchuria occupied a unique niche on China's frontiers because of its inner facing frontier. Under the Qing (Manchu) dynasty, the population beyond the Great Wall was composed of tribal elements "who remained outside of the conquered territory but were identified with the alien dynasty within the Wall." In periods of alternating barbarian and Chinese ascendancy, Manchuria served as a reservoir of officials and troops. The indigenous population and the colonists from the south looked back to China rather than forward to settling new territories (Lattimore, 1940, 1962). The Manchu policy of restricting immigration into their homeland broke down in the late nineteenth century, and a process of sinicization gradually erased the ethnic frontier between the Han Chinese core and Manchuria.

On the frontier with the Mongol tribes, the intermingling of the Chinese and the steppe peoples shaped an ethnically and economically diverse ecology. Here the expansion of the Qing and Romanov Empires separated the Mongol tribes into three parts, those living under Chinese rule in Inner Mongolia, under Russian rule in Buryat Mongolia, and in a state of independence in Outer Mongolia. However, all continue to cherish memories of unity under the legendary rule of Chingghis Khan.

Beginning in the 1980s, Western scholars began to move away from the focus on the maritime frontier and follow up on Lattimore by arguing that the interaction of the sedentary Han Chinese population with the nomads along the Inner Asian frontier established precedents for subsequent dealings with the Western colonial powers on China's coastal frontier. The process was guided by bargaining for mutual benefit. Its main features were the regulation of trade, religious toleration, and the establishment of a tribute system (Fletcher, 1986; Barfield, 1989; Jagchid and Symonds, 1989). From these studies, the nomads emerge as more dependent and hence more committed than the imperial power to the maintenance of an exchange culture on the frontiers. They clearly preferred trading to raiding. As long as the nomads accepted Chinese cultural superiority and tributary status peace was assured. Throughout the eighteenth century, the Qing dynasty pursued an active frontier policy in the mixed Muslim and Turkic populations of the northwest (Gansu and Xinjiang). Preoccupied by the Inner Asian frontiers, which were traditionally regarded as posing the greater threat, its leaders failed to judge accurately the new challenge on its maritime frontiers beginning in the early nineteenth century. Belatedly, they responded by employing the same tactics of conciliation with the Western maritime powers that they employed in Inner Asian frontiers with disastrous results. From the Opium War in the 1840s to the Boxer Rebellion in 1900, the Chinese steadily lost control over their maritime frontier to the Western naval powers and Japan. By the end of the century, they confronted the prospect of also losing control over the Inner Asian frontiers to the Japanese or the Russians.

In the last decade of the Qing dynasty, Chinese officials in Manchuria strengthened their military defense of the frontier. They invoked the time-honored strategy of using barbarians against barbarians. This time it was not the nomads but the great powers who assumed the role of barbarians. The Chinese sought to balance the Russians and Japanese with the United States as a part of their frontier defense in Manchuria. The effort failed because the United States was unwilling to transform its Open Door Policy from an abstraction to an active participation in economic development backed up by a political commitment. Under similar circumstances, the Nationalist Government of Chiang Kai-shek attempted to exploit the renewed American endorsement of the Open Door in its defense of the Manchurian frontier against the Japanese in the 1930s and the Russians in 1945 with equal lack of success.

The next important stage in the reconceptualization of the Chinese frontier policy came in the 1990s from a group of scholars who insisted that the Qing was an Inner Asian empire rather than a Chinese dynasty. They argued that a Manchu ethnic identity did not diminish but grew stronger throughout the nineteenth century as the new ruling elite maintained the frontier between their homeland and China. For them sinicization was based on the mistaken view of the Han people as a homogenous ethnic group (Crossley, 1997, 1999; Rawski, 1998; Milward, 1998). Their revisionist view of the frontier in Chinese history has attached new and unprecedented importance to the complex interaction between the core provinces of China and the Inner Asian frontiers. This perspective has stimulated comparisons between the Chinese, Russian, and Ottoman frontiers (Perdue, 2005). The Chinese Revolution and Civil War ending in 1949 revived the process of sinicizing the frontier provinces of Tibet, Xinjiang, Inner Mongolia, and Manchuria and created a new frontier along the state borders with the Russian Republic.

Ottoman Frontiers

The Ottoman concept of frontiers emerged from the fusion of three traditions that shaped its self-identification as a state: the nomadic warrior, the Islamic religious, and the Byzantine imperial. The founders of the Ottoman frontier thesis, Paul Wittek and Mehmet Fuad Köprülü, made a distinction in the early period of Ottoman expansion between the core and frontier in terms of social structure and cultural characteristics. Köprülü, influenced by the Annales School, took a broader view of the frontier embracing its distinctive religious, legal, economic, and artistic institutions. Wittek stressed the gazi warrior milieu rooted in Islamic religious zeal. By the thirteenth century, he argued, warrior cultures appeared on both sides of the porous Turkic-Byzantine frontier. They were originally composed of Islamic *gazis*, and Greek *akritai* increasingly replaced by Turkmen tribesmen recruited from the other side. In this intermediate zone, war and trade often alternated in a pattern similar to that on Roman and Chinese frontiers and facilitated the penetration and conquest of the Byzantine Empire by the Ottoman Turks (Wittek, 1938).

The concept of the early Ottoman Empire as a gazi state, one emanating from an Islamic warrior culture, has run into as much scholarly opposition as the Turner thesis in the United States. It is now clear that gazi meant different things to different people as reflected in the frontier narratives and subsequent Islamic religious texts. Over the centuries the various interests – rulers, border warriors, and ulema – vigorously promoted their own views of what gazi activity meant. The current view is that like so many terms employed in the attempt to construct a founding myth gazi has always been highly contested. Recent interpretations substitute for the 'Ghazi Thesis' an Islamo-Christian syncretism and expand the time frame, broaden the context to include the larger Islamic world, reexamine the sources critically, and factor in the spatial distance of the frontier from the distant central state (Darling, 2000; Lowery, 2003). One thing is certain: no longer can the early Ottoman frontiers be equated with the idea of jihad or holy war. However, there is no denying that it represented the frontier spirit in Ottoman state building.

Jihad, a term with both military and spiritual aspects derived from the precepts of Islam, was employed by the Ottoman ruling elite to represent the division of the world into two cultural spheres, *dār ul-Islām*, the abode of Islam, and the *dār ul-harb*, the abode of war. Between them lay a frontier zone a contested territory where warriors fought the just war consecrated by Islam. This provided the ruling elites with a justification for the expansion of the frontiers in all directions, but this rigid duality could not be strictly maintained. The Ottoman rulers created frontier marches (*uc*) under the leadership of frontier lords who enjoyed considerable autonomy. In return, they were obliged to furnish armed men, both Muslims and Christians, as frontier troops. The image of the Islamic warrior tradition eroded over the following centuries, bringing change to the concept of frontiers.

The expansion of the Ottoman frontiers was an almost a continuous process from the fourteenth century to the late seventeenth century. The Sultans adopted pragmatic and flexible strategies to deal with the great variety of frontiers, particularly those in Hungary, Kurdistan, and Eastern Anatolia. In the first case, joint administration by Hungarian and Ottoman officials did not check the border raiding by the frontier troops on both sides, often joined by hayduks. The peasantry formed local self-defense forces called *paraszt vármegye* (a peasant county) by the Hungarian and *zapis* ('the enlistment') by the Slavic population, but they too often behaved more like insurrectionists than forces of order. Similar experiments were tried on other frontiers, often certified by the Ottoman authorities. At the height of its power from the fourteenth century to the end of the seventeenth century, Ottoman rule preserved and in some cases expanded the role of nomadic tribes, creating 'a moveable empire' (Kasaba, 2009). The nomadic tribes performed important functions throughout the empire in providing networks of trade and communications but were especially valued on the expanding frontiers. They were used to occupy conquered areas where the political structures were weak and local communities disrupted or dispersed. They operated as a powerful military force in the early centuries when cavalry was the dominant branch of armies. In the fourteenth century in the Balkans, the spontaneous migration of 10 000 nomads linking up with Vlachs and Albanians prepared the way for subsequent conquest by the regular army. The rulers devised special rules for regulating tribal affairs. They classified the tribes and appointed tribal officials to administer and collect taxes. They governed relations between the nomads and sedentary population and protected the migratory routes. The end of the period of rapid expansion and the first big loss of territories following the long war with the Hapsburgs in 1699 began the process of restricting the movement of nomads and attempting to settle them on vacant or underpopulated land. This coincided with a reevaluation of the symbolic frontier that in theory separated the Islamic Ottoman polity from its Christian neighbors. The closing of the frontier in 1699 was followed by an almost steady retreat of the frontiers as the result of wars with the Habsburg and Russian Empires and the rebellions of the orthodox population in the Balkans. By the early twentieth century, the Ottoman Empire had become a largely Muslim state with frontiers in Europe reduced to a small strip of territory shielding Istanbul. The collapse of the Empire meant a further shrinking of the frontiers in Asia and the reconstitution of the state boundaries along more generally Turkish national lines, with the important exception of the Kurds whose demands for autonomy kept the eastern frontiers fluid.

Functional Approaches to Grammar

William Croft, University of New Mexico, Albuquerque, NM, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by W. Croft, volume 9, pp. 6323–6330, © 2001, Elsevier Ltd.

Abstract

The term 'functional' or 'functionalist' has been applied to any approach to grammar that puts the primary emphasis on explanation in terms of factors outside the formal structure of language. The four most significant functional approaches can be characterized in terms of the types of functional explanations that are put forward and the position taken vis-à-vis formalist explanations of grammar. More recently, a dynamic, usage-based approach to the functionalist analysis of grammar has been developed.

Introduction

The term *functional* or *functionalist* has a meaning in linguistics distinct from the use of the term found in anthropology, sociology, or philosophy. In linguistics, a functional analysis is an analysis of linguistic structure that puts the primary emphasis on explanation in terms of factors outside the structural form, such as meaning or the function of language in discourse. Functional analysis is in contrast to *formal* analysis, which is an analysis of linguistic structure that puts the primary emphasis of explanation on principles defined purely in terms of structural form. The term *functionalist* has been applied to any school of grammatical analysis which argues for the primacy or centrality of functional explanations over formal explanations.

Such a broad characterization of functionalism in linguistics, of course, requires further elaboration. We begin by illustrating the commonest types of functional explanations, and then turn to different schools of linguistic theory that call themselves functionalist.

Types of Functional Explanations

There are three types of functional explanations that usually are distinguished in the functionalist linguistic literature: processing, cognitive, and discourse or information structure explanations.

Processing Explanations

Processing explanations make reference to models of the production and comprehension of utterances. A processing explanation argues that some aspect of grammatical structure is due to limitations on the human ability to produce or comprehend the structure.

Processing explanations typically are employed to account for two sorts of linguistic facts. One is the relative frequency of a particular grammatical structure across the world's languages. For example, it has been observed that suffixes are on the whole more frequent than prefixes (or more complex alterations of word forms) in the world's languages. A processing explanation has been proposed for the suffixing preference. It is hypothesized that speakers process word stems before their inflections. Psycholinguistic experiments imply that the beginning of a word is most salient, hence the word stem should ideally occupy the initial position; the ends of words are the next most salient, hence inflections should ideally occupy the final position.

The second sort of phenomenon for which processing explanations are employed is to account for degrees of acceptability of a construction in a single language. For example, in English, subordinate clauses embedded in the middle of a clause are relatively less acceptable than subordinate clauses embedded at the end of a clause: compare *I know the boy that owned the cat that caught your parakeet* to *The parakeet that the cat that the boy I know caught died*. This fact has been explained as a consequence of the difficulty in interpreting the latter sentence's center-embedded clauses. In fact, it is grammatical in English to move a relative clause from the middle of a clause to the end under certain circumstances: *A woman contacted me who I had shared an apartment with during my last year at college*.

Processing explanations have been proposed for constraints on certain types of syntactic structures, constraints on patterns of morphemes within words, and on sound patterns. The latter explanations typically are described in terms of ease of articulation or ease in discrimination (in speech perception). Processing explanations for syntax and morphology, especially in explaining differences in cross-linguistic frequency of word order and morpheme order, are particularly associated with the work of J. Hawkins (e.g., Hawkins, 2004).

Cognitive Explanations

Cognitive explanations generally make reference to the conventional meaning of a word, inflection, or syntactic construction (e.g., Bybee, 2010; Tomasello, 1998/2003). A cognitive (semantic) explanation of a grammatical phenomenon essentially hypothesizes that some or all aspects of the analysis of the grammatical phenomenon make reference to conventional semantic properties. For example, some languages have plural inflections for all count nouns, while other languages restrict plural inflections to only nouns referring to animate beings, still others to only nouns referring to humans. This variation is built on a general ranking or hierarchy of nouns according to the semantic class of their

referents: human < animate < inanimate. The description of the constraint on the occurrence of the plural inflection in each language, and the cross-linguistic pattern of constraints, requires reference to the semantic classes of entities denoted by the noun, described in terms of animacy.

Cognitive explanations, like processing explanations, have been used to describe both grammatical constructions in particular languages and also patterns of cross-linguistic variation. The example of the animacy hierarchy in the preceding paragraph illustrates both sorts of explanations. It hypothesizes that the distribution of the plural inflection in any particular language will make reference to the semantic class of the entity denoted by the noun. It also hypothesizes that the cross-linguistic variation in the distribution of the plural inflection is subject to the hierarchical ranking of animacy categories given in the preceding paragraph. In recent cross-linguistic research (see Croft, 2001, 2003 and references cited therein), explanations of cross-linguistic patterns have been offered in which the patterns of occurrence of a construction are mapped onto a single semantic or conceptual space applicable to all languages.

Some cognitively oriented functionalists make a stronger claim about the relationship between grammatical form and semantic function, namely that certain grammatical categories are better described in semantic terms. This hypothesis will be discussed below on the contribution of cognitive linguistics to functionalism.

Discourse (Information Structure) Explanations

Discourse explanations make reference to the organization and presentation of information in discourse, that is, the structuring of information for the purpose of communication. Such explanations are called discourse explanations by some functionalists, and information structure explanations by other functionalists. For example, the English active and passive voice constructions (*The car hit the tree* vs *The tree was hit by the car*) both describe the same event and participants, but differ in which participant is encoded as the subject of the construction. It has been argued (based on naturally occurring examples) that the participant that is more topical is encoded as subject. Another example is the choice of construction in response to a question such as *Wasn't that incredible when Mary called the boss a pig?* One can respond with *Yeah, it really shocked me that she called him that*, but not with **Yeah, what really shocked me was that she called him that*. The unacceptable response uses the pseudocleft construction, and the pseudocleft construction is acceptable only if the information 'something really shocked me' is already in the hearer's consciousness. It is not in this case, and hence is unacceptable.

As with processing and cognitive explanations, discourse functional explanations have been offered both to explain restrictions on the acceptability of specific constructions in particular languages and to explain the frequency of distribution of particular linguistic features across languages. Examples of the former were given in the preceding paragraph. An example of the latter is certain patterns of word order. In the overwhelming number of languages, the subject precedes the object in the most common order of elements in a clause. It has been proposed that the reason for this asymmetry is that the subject tends to be the topic, and the most common discourse pattern is for the topic to precede the 'comment' or at least other less topical participants.

Schools of Functionalist Analysis

One of the most fundamental issues that divides schools of linguistic theory is: what is the relationship between linguistic form and linguistic function? The relationship is not at all straightforward. Also, depending on the position that a linguist takes on the relationship between form and function, certain additional hypotheses have to be made in order to accommodate linguistic facts. These hypotheses have to do with aspects of language not directly connected to the form–function relationship, such as the organization of grammatical knowledge in a speaker's mind, the nature of semantics, and the role of cross-linguistic evidence. Since these additional hypotheses are closely associated with various schools of functionalist analysis, they will be discussed here.

Functionalism and Formalism

Functionalist schools generally set themselves up as contrasting with the formalist approach, associated most strongly with N. Chomsky, but also advocated by other linguists who reject some of Chomsky's more specific claims about syntax. A purely formal explanation of a grammatical phenomenon makes reference exclusively to properties of grammatical form or structure. With respect to grammatical structure, a formal explanation of some pattern of sentence structure will make reference only to syntactic categories and structural relationships between the elements of a sentence, and not to the meaning of the words, inflections or constructions of that sentence, their discourse function, or their production and comprehension in language use. With respect to word structure, a formal explanation will make reference only to morphological categories and relations between roots and affixes, and not to aspects of the meaning and use of word forms. With respect to sound structure, a formal explanation will make reference only to the structure of the sound system independent of its articulatory and auditory realization.

The concept of a formal explanation is closely associated with the theoretical position that the organization of grammatical knowledge in a speaker's mind is divided into components which separate a linguistic form from its conventional meaning and use in discourse. A typical model describes grammatical knowledge as being compartmentalized into phonological, syntactic, and semantic components. The phonological component is separated from its phonetic realization, and the syntactic component is separated from its semantic interpretation. Linguistic form is linked up to its phonetic realization or semantic interpretation, eventually: formal models have rules linking syntax to semantics and phonology to phonetics. The formalist hypothesis does however imply that linguistic form is organized in a purely formal way to a high enough degree that it can be described best as existing in separate components. That is, the formal analysis of grammatical structure is self-contained relative to functional factors.

Functionalist approaches to language challenge or reject the formalist model of the relationship between form and function to varying degrees. However, all functionalists accept that not all aspects of grammatical structure can be accounted for by meaning and use. There will always be some degree of arbitrariness in language structure, where arbitrariness is intended to mean not wholly explainable in terms of language function. The question is, how much arbitrariness is there in language structure, and to what extent does the arbitrary aspect of language structure form a self-contained system? Different functionalist schools give different answers to this question.

Autonomous Functionalism

The closest approach to formalism which calls itself functionalist can be called *autonomous* functionalism. Autonomous functionalism argues that the number of properties of grammatical form that are explainable solely in grammatical terms are considerably fewer than most formalist theories assume. In particular, the restrictions on the use of particular constructions are sought in functional properties, whether cognitive, processing, or discourse-functional. To take a simplified example: in the *There*-construction (as in *There is a bird in the bushes*), a noun phrase with an indefinite article (*a bird*) is acceptable but one with a definite article usually is not (compare **There is the bird in the bushes*). A plausible explanation for this restriction is that the *There*-construction is used to introduce a new referent into the discourse, but definite noun phrases describe referents already known to both speaker and hearer. This would be an autonomous functionalist analysis of the restriction.

However, even in an autonomous functionalist approach, the rules governing the formation of the construction itself, such as the fact that *There* is the first element followed by a form of *be*, are considered to be purely formal. Autonomist functionalists focus their research efforts on accounting for as many of the constraints on the construction as possible in terms of functional properties, while leaving the basic structure of the construction for formalist analysis. The autonomist functionalist research program is found in the work of S. Kuno, E. Prince, G. Ward, and their students and associates. Their explanations generally appeal to properties of information structure rather than semantic properties. Because they accept the basic structural analyses of formalist approaches, autonomous functionalists generally do not reject the view that linguistic knowledge in a speaker's mind is organized into components. Instead, they have proposed that there is another component, the information structure component, which should be included along with the syntactic and semantic components.

In fact, many functional analyses of specific constructions in more radically functionalist approaches to language are actually autonomous functionalist analyses, that is, they account for the restrictions on syntactic constructions in terms of the meaning and use in discourse of the construction. We may call these autonomous functional analyses in whatever sort of functionalist approach they are found in. That is, autonomist functionalist analyses of particular constructions are not incompatible with more radical functionalist approaches.

Mixed Formalism/Functionalism

Another sort of approach, not clearly identifiable with any particular school of linguistic theory, but sometimes called functional, challenges the hypothesis of a sharp separation between the use of formal or functional properties to describe grammatical constructions. In these theories, the description of both the structure and the constraints on a construction can mix formal and functional properties. Two schools, *Functional Discourse Grammar* of S. Dik and K. Hengeveld and associates and *Role and Reference Grammar* of R. Van Valin and associates, both use formal and functional properties (typically semantics, but also information structure) to describe the grammatical structure of sentences as well as the constraints on them. In addition, many grammatical descriptions of languages informally describe both syntactic and semantic properties of constructions without implying any sharp division between the two.

Typological Functionalism

As was noted above, cognitive, processing, and discourse explanations have been offered for patterns of cross-linguistic variation as well as in the analysis of the grammars of individual languages. A school of linguistic theory known as typology has arisen which focuses on cross-linguistic variation and its limits (see, for instance, Comrie, 1989; Croft, 2003; Givón, 2001; Greenberg, 1990). Much cross-linguistic variation appears to be built on the base of general functional patterns, as illustrated above for cognitive, processing, and discourse explanations. This observation has led some typologists to argue that all cross-linguistically verified universals of language are susceptible to functional explanation in this way. This approach to analysis is called typological functionalism or the functional–typological approach.

Typological functionalism makes a stronger claim than the schools described in the preceding sections. The autonomous functionalist approach assumes that there still remains a significant amount of syntactic structure that can be described in terms of a self-contained set of rules (which are further assumed to be in part language-universal). The mixed formal–functional theories do not assume that formal principles governing syntactic structure are self-contained, but those theories allow for the possibility that there are formal properties of languages that are universal for all languages. The typological functionalist approach hypothesizes that any universal generalizations about linguistic structure are ultimately explained in functional terms.

The typological functionalist approach does not, in fact cannot, assume that the structure of a particular language's grammar is entirely explainable in functional terms. For instance, one example given above was that the occurrence of a plural inflection on nouns could be accounted for by the hierarchy human < animate < inanimate. The semantic hierarchy is universal, but each language applies the hierarchy to the distribution of the plural inflection in its own way, that is, one cannot predict what semantic class a language will extend (or restrict) its plural inflection to. That is, the exact class of nouns allowing a plural inflection is partly arbitrary, although

it is partly explainable in terms of the semantic hierarchy: if the language allows plural inflection for animate nouns, it will allow plural inflection for human nouns. This sort of explanation of a linguistic phenomenon is sometimes described as motivation, in contrast to a set of rules that exhaustively predicts the forms that would be found.

A typological functionalist analysis must allow for some degree of arbitrariness in accounting for cross-linguistic patterns. If there were no arbitrariness, all languages would be alike in their grammatical structure; and they are not. But the typological functionalist approach hypothesizes that the arbitrary aspects of language structure are language specific, and that any universal generalizations about linguistic structure are ultimately explained in functional terms.

An important element of typological functional explanations is the hypothesis of iconicity or iconic motivation, in which grammatical structure is hypothesized to reflect semantic or conceptual structure to some degree. For example, the closer grammatical relationship between verb and object as opposed to verb and subject in many languages is attributed to the closer semantic relationship between states of affairs and the participant usually encoded as the object. Iconic motivation can be used to account for grammatical structure itself, not just constraints on grammatical structures. In this respect, typological functionalism represents a more radical functionalist approach than autonomous functionalism.

Cognitive Linguistics and Functionalism

Cognitive linguistics (e.g., Lakoff, 1987; Langacker, 2008; Talmy, 2000) is a broad school of linguistic theory that is usually called functionalist. Cognitive linguistics, as its name indicates, focuses on cognitive (semantic) explanations for grammatical structure. Cognitive linguistics has contributed a number of ideas to other functionalist approaches that are relevant to assessing functional approaches.

Cognitive linguistics has proposed a model of grammatical knowledge, construction grammar, that offers an alternative to the formalist model in which form and function (semantics and information structure) are separated in distinct components (Croft, 2001; Goldberg, 2006). Construction grammar hypothesizes that knowledge of syntax involves the knowledge of individual constructions which combine formal properties (syntactic structures, morphological inflections) and functional ones (semantics and discourse function). For example, the ditransitive construction [X Verb Z Y], as in *Marilyn sent Gina a book*, specifies not only the syntactic structure of the construction but also the semantic relationships among the participants, such as the fact that Z comes to possess Y, by virtue of the form of the construction (in this case, two object phrases, referring to Z and Y, respectively, immediately following the verb). Constructions are organized in a network of grammatical knowledge in a speaker's mind. More broadly, grammatical knowledge is organized as a system of signs or symbols, consisting of form (the signifier) and function (the signified). A model organizing grammatical knowledge in terms of constructions/symbols/signs allows for a direct statement of functional properties that are relevant to particular grammatical constructions and other grammatical units.

Cognitive linguistics argues that semantics involves conceptualization or construal of an experience by a speaker for the purposes of linguistic communication. For example, an English count noun can be used in a mass noun grammatical context, as in *There was a huge Buick there; just acres of car* (attested example). The noun *car*, normally denoting an individuatable object, is construed to denote the size dimension, which is unbounded, in the noun phrase construction lacking a determiner. These and other examples indicate that the English count noun–mass noun distinction has at least some semantic basis. Cognitive linguists also accept that some alternative construals are conventionalized, such as *chicken* (meat, mass noun) vs. *chicken* (live bird, count noun). Nevertheless, the conventionalized grammatical distinction conforms to the semantics of count noun vs. mass noun: a live bird is an individuatable entity, while meat is an unbounded substance.

Conventionalized construals are of course partly arbitrary (see below); but the semantic regularity of both conventional and novel construals has led cognitive linguists to argue that even grammatical categories such as 'noun' and 'subject' are susceptible to a cognitive semantic explanation. That is, a grammatical category such as 'noun' encodes a construal of an entity in a certain way, which can be discerned by the occurrence of particular word roots directly as nouns, and in the semantic changes that occur when a non-noun root is used as a noun (for example, *a dance* reifies the act of performance and defines it as a particular sequence of steps), or can be morphologically derived as a noun (for example, *a musical composition* refers to the product of the act of composing).

Finally, cognitive linguistics has developed a model of categorization, which has in turn been exploited by functionalist linguists. A classical view of meaning is that the meaning of a word, inflection, or grammatical category must be a single definition that will cover all and only the appropriate uses of the word or category. Cognitive linguists have argued that many word and category meanings can be described in terms of polysemy, that is, distinct but semantically related meanings. For example, the meaning of *over* in *The bird flew over the hill* (path of motion) is distinct from its meaning in *The house is over the hill* (location), but they are related systematically. More specifically, cognitive linguists (drawing on research by psychologists) have suggested that many polysemous categories have one meaning that can be considered central or basic, called the category's prototype. Cognitive and other functionally oriented linguists have argued that many if not all grammatical categories are in fact polysemous, and many of these categories have a semantic/discourse-functional prototype which is found to be valid across languages (*see* Prototype Theory in Linguistics).

Functionalism and the Dynamic Approach to Grammar

Grammatical structure is commonly assumed to exist in speakers' minds. However, grammatical structure is also directly involved in social interaction in language use, and language use is central to accounting for language acquisition, language variation, and language change. In the more dynamic process of language acquisition and language change, functional factors have been argued to play a role.

In both language acquisition and language change, it has been argued that competing motivations among functional principles play a major role. The idea of competing motivations is that (functional) principles may come into conflict such that there is no grammatical system that satisfies all of the functional principles. As a result, change occurs over time in acquisition and in the history of a language, and the languages of the world exhibit structural diversity even though their speakers' linguistic behavior conforms to the same functional principles. (Competing motivation models do not presuppose that the competing principles are functional, and in fact competing motivation models are now used by many formalists; see below.)

The most general and commonly offered example of competing motivations is that between economy and iconicity (*see* Iconicity in Linguistics). *Economy* is the principle that a speaker uses the least effort necessary to express himself or herself. For example, English leaves the singular number of nouns unexpressed: *book* vs *book-s*. Economy is considered to be a speaker-oriented functional principle: its influence on language is for the benefit of the speaker. *Iconicity* is, in part, the principle that all of the relevant parts of the meaning conveyed are in fact conveyed by grammatical elements in the utterance (words, inflections, etc.). For example, in some languages, both the singular and the plural of a noun are expressed by overt suffixes. This aspect of iconicity is considered to be hearer oriented: any aspect of meaning left out by the speaker may not be recoverable by the hearer. Economy and iconicity compete with each other: a linguistic expression that is economical will not be iconic (since it leaves some elements of meaning unexpressed), and an expression that is iconic will not be economical (since certain elements of meaning are not left unexpressed). Hence, across languages, there is diversity in the expression of the category of number, and languages change from one form of expression of number to another over time.

Competing motivations models have been proposed in language acquisition (Bates and MacWhinney, 1989) and in language change (Haiman, 1985). More recently, some functionalist linguists (P. Hopper, R. Langacker, J. Bybee, W. Croft) have emphasized the dynamic character of language in ordinary use, and have argued that a speaker's grammatical knowledge should not be considered to be as static and immutable as is usually believed. They argue that a speaker's grammatical knowledge is not a tightly integrated system, but rather a more loosely structured inventory of conventionalized routines that have emerged through language use. The empirical research of the functionalist linguists who advocate this view has focused on the role of frequency of use on the entrenchment of grammatical knowledge, and on inductive models of abstracting grammatical knowledge from exposure to language use, both in acquisition and in adult usage.

These functionalists have argued for a usage-based or exemplar-based view of grammatical representation, in part following recent proposals in phonology. In the exemplar view, all tokens of grammatical units (words, constructions, etc.) to which a speaker has been exposed are at least initially stored as part of the mental representation of that grammatical unit, as a cloud of exemplars. The exemplars are structured qualitatively by dimensions of conceptual space (analogous to phonetic space), and processes in memory lead to their consolidation, entrenchment, and decay. These processes are dynamic processes that lead to changes in grammatical representation in the lifetime of an individual speaker.

Directions and Prospects for Functional Approaches to Grammar

Taken as a whole, functional approaches to grammar are widely practiced in linguistics. Nevertheless, there are important divisions between different schools of functionalist theory and between functionalists and formalists.

A common misunderstanding (among formalists in particular) is the belief that functionalists do not accept the existence of *arbitrariness* in language, that is, that not all aspects of grammatical knowledge are explainable by functional principles. There is no functionalist that holds that view. However, many functionalist theories have not developed a model of the representation of grammatical form, instead focusing their attention on the analysis of functional domains and their role in accounting for grammatical structure. There are significant exceptions to this observation, notably the mixed formal/functional theories, Bybee's model of lexical and morphological representation, and construction grammar in cognitive linguistics. Construction grammar is gaining a wider audience, and some functionalists are beginning to develop more detailed models of grammatical structure that are compatible with functionalist theories.

A significant split in functionalism is between those who are more cognitively oriented, focusing their attention on cognitive explanations, and those who are more discourse oriented. These two functionalist approaches have largely gone their own ways, developing models of language meaning (cognitive linguists) and language in use (the discourse functionalists). However, there are some functionalists such as T. Givón and W. Chafe whose work draws on both cognitive and discourse models. Usage-based models integrate cognition and discourse, in that there is a feedback relationship between the mental representation of linguistic knowledge and language use. The two approaches are inherently compatible: language must be understood from both a psychological and a social-interactional perspective.

Functionalist approaches to language generally have also neglected research in sociolinguistics (*see* Sociolinguistics). Sociolinguistics begins with the hypothesis that language is a dynamic, variable phenomenon, and argues that factors outside linguistic form, namely social parameters, account for variation and change in language. In both of these respects, sociolinguistics shares theoretical assumptions in common with functionalism. The increase of research on social-interactional factors and on relative frequency of use in functionalist research may lead to an integration of social with other functional factors in a social-functional theory of linguistic variation and change.

A rapprochement between functionalism and formalism is less likely, because the two differ in fundamental assumptions about the nature of language and the relation between form and function. There are some respects in which practical research is converging among formalists and functionalists,

however. For instance, competing motivations as a mechanism of analysis is now widely used in formalist theories under the name of *Optimality Theory*. The rise of computer-aided corpus research has led to a convergence in interests on naturally occurring language and the role of usage in grammatical structure. Some formal semanticists have made reference to prototypes and polysemy, and some semanticists working in generative grammar also give conceptualization a significant role in analysis.

Abstract

Brain imaging and brain mapping techniques are major tools in language research and language rehabilitation. While this section aims to introduce the reader to the major techniques used in the study of language, it also wishes to raise the reader's awareness of the limitations of each of these methods. This discussion includes electroencephalography, magnetoencephalography, positron emission tomography, functional magnetic resonance imaging, density tensor imaging, functional near-infrared spectroscopy, transcranial magnetic stimulation, and transcranial direct current stimulation. The strengths and weaknesses of each of these methods – as well as examples of how these techniques have been applied to the study of language – follow explanations of how they function.

Introduction

Over the past 30 years, functional neuroimaging and brain mapping techniques have emerged that would have exceeded the wildest dreams of scientists 50 years ago. Findings derived from these techniques have given rise to cognitive neuroscience, a field in which questions in cognitive psychology are investigated with brain imaging techniques. Brain mapping attempts to relate the brain's structure to its function (or vice versa) in health or disease, or investigates how the brain changes physically in response to external or internal influences such as the aging process or learning and so on. Functional neuroimaging and brain stimulation techniques can be used to map brain functions. Functional neuroimaging techniques attempt to measure neuronal activity in the brain and relate this activity to behavior. There are basically two ways of doing so. One is by measuring changes in electrical or magnetic activity when neurons become active (electroencephalography (EEG) and magnetoencephalography (MEG)), and the other is by measuring the metabolic changes due to energy consumption of the active neurons (positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and functional near-infrared spectroscopy (fNIRS)). Brain stimulation techniques such as transcranial magnetic stimulation (TMS) and transcranial direct current stimulation (tDCS) influence brain structure and function through magnetic or electrical fields.

Regardless of the technique used, the research findings obtained are usually presented as colorful brain images that exert a curious fascination in academics, lay people, and media alike.

'Seeing is believing' is both a promise and a threat for those interested in brain science. Evolution has gifted us humans with an exquisite sense of sight that allows us to 'see how the world around us works' and part of that world is our own brains. In general, vision serves us well, but the ancient threat of mirages, of 'seeing things that aren't there,' is a constant companion when we read titles such as 'the anatomy of language.' Without language, understanding complex phenomena would be impossible, but language can not only elucidate, it can also obfuscate and confuse – and the tendency to confuse image with reality, to inappropriately reify images into something material is nowhere more treacherous than in neuroimaging (Bennett et al., 2007).

Caution must be applied when discussing how a piece of living meat, the brain, processes information. The images to be discussed in this chapter are perhaps best considered as parallels with their etymological counterparts, 'imaginations.' These 'pictures' are not technical diagrams to help understand the workings of a machine whose purpose is known, but rather they are highly abstract syntheses of thousands of infinitesimal phenomena framed in a theory that attempts to demonstrate how they may be directly associated with linguistic meaning. Further, images of brain activity only have meaning when the acquisition of the data on which they are based are acquired using the appropriate experimental design, the correct analyses, and when they are interpreted with care.

Each of the methods described below has its own strength and weakness; what they have in common is that they are limited by the physical properties of the system itself and by the way the brain works, or, in other words, the physiology of the brain.

Every image based on neurophysiological data is characterized by the degree of its resolution in space and time. The spatial resolution (or 'sharpness') of fMRI, for example, is on the order of a few millimeters but this relative 'sharpness' comes at the cost of long 'exposure times': fMRI images demonstrate events that unfolded in the brain over a period of several seconds. Images derived from EEG or MEG, on the other hand, demand only a few thousandths of a second (milliseconds) 'exposure time' but, compared with fMRI, these images are 'blurred' over large areas of the brain.

Compounded with basic limitations inherent in all neuroimages, one must add further possible distortions that can arise from the individual measuring devices themselves. Each measuring instrument is susceptible to artifacts generated by its own internal programming or by interference from nonneural tissue (the pulsation of the blood, for instance and, to a lesser extent, that of the cerebrospinal fluid). Further artifacts can arise at interfaces between/among various physical phases (solid, liquid, gas) of the tissues depicted in the images: scalp,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54009-4

skull, air-filled sinuses, membranes, blood, spinal fluid, and brain.

A satisfactory, simple explanation of how some of the methods discussed in this chapter work is not always possible. To understand, for example, how images from fMRI or MEG are generated demands a basic knowledge of Maxwell's laws of electromagnetism and elementary quantum mechanics, prerequisites that some readers may not possess. The good news, however, is that a working knowledge of these methods is within the reach of anyone with high school knowledge of electricity, magnetism, and simplified quantum theory. Part of this working knowledge includes knowing the benefits and limitations of each method. A discussion of these factors is found at the end of each of the following sections.

And, finally, the images produced by these methods are susceptible, not only to distortions produced by the measuring instrument itself and from interactions between the measuring instrument and the brain, but the brain-being-measured is also influencing *itself* by sustaining its vacillating psychological states of wakefulness/sleep/high-arousal/interest/fear or pain, and so on.

Trying to measure isolated neural activity associated with a particular brain task is a bit like trying to record the sound of a single flute during a musical festival in which several huge bands are loudly playing different songs simultaneously under the same roof. Whatever the object of the investigator's interest is, most of the brain will be actively doing something else at the same time: controlling the heartbeat, maintaining the sitting position, looking out for danger, and so on. With respect to energy demand, the brain is a very active organ: it has been calculated that although the brain represents only 2% of the body weight, it accounts for about 20% of the body's total energy consumption, and most of this energy ('dark energy') is unaccounted for by its responses to external stimuli (Raichle, 2006; see **Figure 1**).

Even given an adequate understanding of the imaging methods described below, it seems certain that new possibilities of misinterpreting neuroimages will continue to emerge and skepticism in science will always remain a cardinal virtue.

Functional Neuroimaging Techniques Based on Electromagnetism

The human brain contains various types of nerve cells (neurons) that communicate with each other via chemical and electrical signals. Information transfer from the cell that sends out information (presynaptic neuron) to the cell that receives the information (postsynaptic neuron) occurs at the synapse. Coherent postsynaptic activity of thousands of co-aligned pyramidal cortical neurons gives rise to electric and magnetic field changes that can be measured on or near the scalp. A technique that measures noninvasively *electric* fields is EEG and a technique that measures *magnetic* fields is MEG. EEG records electric field changes that arise from components of the postsynaptic currents that are oriented tangentially *and* radially with respect to the scalp, whereas the MEG measures the tangential component of these currents exclusively and is thus most sensitive to activity in the cortical sulci.

Electroencephalography (EEG)

The first measurement of human brain activity – in the form of minute changes in electrical potential measured between two locations on the scalp – was reported in 1924 by the German physiologist and psychiatrist, Hans Berger. A graphic recording of these voltage changes over time is called an 'electroencephalogram' (EEG) (see **Figure 2**). An EEG is the blurred result of huge numbers of neurons discharging at roughly the same time (in synchrony) compared with a huge number of other

Figure 1 fMRI images of spontaneous brain activity in the absence of a task while the brain is at 'rest' (also called resting state). This, of course, does not mean that the brain is not doing anything – it only means that we do not know what the brain is doing and what goes on in a person's mind. It is assumed that the activity we 'see' when the brain is at 'rest' represents intrinsic brain activity, represented by correlated spontaneous fluctuations in the fMRI signal. The color scale is an arbitrary visualization of the correlations. In this image, activations (red to yellow colors) and deactivations (blue to green colors) routinely observed in response to attention-demanding tasks are also seen in the resting human brain, that is in the absence of any overt task or behavior. (Left) Lateral and medial views of the left hemisphere; (center) dorsal view; and (right) lateral and medial views of the right hemisphere. Taken from Fox, M.D., Snyder, A.Z., Vincent, J.L., Corbetta, M., Van Essen, D.C., Raichle, M.E. 2005. The human brain is intrinsically organized into dynamic, anticorrelated functional networks. Proceedings of the National Academy of Sciences of the United States of America 102 (27), 9675. Legend adapted by B. Stemmer.

Figure 2 The EEG lab. (a) The subject is being prepared for the recording session. A 128-channel EEG cap has been placed on the head (2). The digitizer (2) is used for marking landmarks on the head and the position of the electrodes in 3D space. This will later allow specification of the anatomical location of the collected EEG signals. To also place a model of EEG generators into the brain, a structural MRI scan of the subject's head and brain has to be obtained in a separate session. The MRI scan is later overlaid ('coregistered') with the data obtained from the EEG. (b) The subject is inside the EEG recording room and watching stimuli on a computer screen (4). The electrode cables from the EEG cap go to the small amplifier box (3). From the amplifier cables go to the data acquisition computer placed outside the recording room. Underneath the amplifier box (not visible in the picture) is a small battery supplying the EEG system with electricity. (c) Outside the recording room a person supervises the EEG recording session. The person can watch the subject inside the recording room through the window (5). On one computer the EEG data are recorded and another computer shows the stimuli the subject sees inside the recording room. neurons discharging at roughly the same time somewhere else in the brain. EEG's have been compared with sound recordings of roaring crowds during sporting events. The voltage changes generated by single nerve cells are vanishingly small when compared with the potentials recorded with an EEG. Therefore, amplifiers are used to enhance the signals and analysis techniques have been developed to extract the signals we are interested in.

In conventional EEG, electrodes are fixed to the scalp (manually or prearranged in an electrode cap or net) and electrically conducting gel, paste, or liquid is applied. EEG signals represent the potential difference measured between two electrodes, an active electrode and the so-called reference electrode. The total number of electrodes used varies depending on the objective of the measurement and can go up to 256 electrodes (so-called high-density EEG). During neurosurgical operations, somewhat more spatially exact EEGs can be recorded by electrodes placed either on or under the leathery dura mater covering the brain. Even better spatial resolution can be obtained by sinking electrodes directly into the tissue of the brain itself (intracortical recordings). No matter where the electrodes are placed, however, the results of an EEG are due to the combined activities of huge numbers of pyramidal cells firing simultaneously and must be seen as a mass phenomenon. Voltage changes recorded from scalp EEGs range between 20 and 100 μV but reach the millivolt range (i.e., are roughly a hundred times stronger) when measured under the dura mater ('subdurally').

In order to plot the voltage changes over time, the recorded voltages must be amplified roughly a thousand-fold and separated ('filtered' in EEG jargon) from the much larger voltage changes that occur, for example, due to muscle artifacts or heartbeat. The amplified and filtered results are then digitally recorded as a function of changing voltage over time and viewed on a computer monitor.

EEG is a direct measure of brain activity in the millisecond range, i.e., EEG has a very good temporal resolution, and is thus particularly suited to investigate 'when something happens' such as specific processes underlying language. A drawback, however, is its spatial resolution, that is 'where something happens.' Since the size of the electrical potential diminishes exponentially with increasing distance from the source, neural activities deep in the brain are difficult to capture. In addition, the electric signals 'spread out' due to volume conduction as they traverse brain tissue, liquids, and the scalp, thus making it difficult to determine from a given pattern of electrical charge observed on the surface of the scalp where in the brain the neural generators are located (so-called inverse problem). To improve spatial resolution of EEG, the number of electrodes on the head can be increased (so-called high-density recording using 60–256 electrodes). Source localization techniques have been developed to identify the loci of the neural activities that give rise to the voltage distribution on the surface of the scalp. With these approaches spatial resolution of EEG has been estimated to be at about 1 cm. Once the sources of the neural

activities are identified in the brain, the exact anatomical location within the brain needs to be determined. This can be done by 'overlaying' the source image with an anatomical brain scan.

The information we can derive from an EEG depends on the analysis technique we use. For clinical purposes, for example, it is often sufficient to decompose the EEG signals into specific 'brain waves' as they are popularly called, such as alpha waves (7–12 oscillations per second, i.e., 7–12 Hz) associated with a relaxed but awake state, beta waves (13–20 Hz) associated with a more aroused mental state or very high-frequency oscillations such as gamma waves (>30 Hz) associated with higher cognitive functions. Although neglected for a long time, decomposing EEG signals through spectral decomposition, so-called time-frequency analyses, has – in the meantime – also attracted the attention of researchers interested in language. In combination with other analysis approaches, one can, for example, isolate components one is especially interested in and determine their sources in the brain and how they are connected to other components (see Figure 3). Special analyses techniques have also been developed to study how individual subjects perform on single trials in an experiment, this is particularly useful in children and patient populations. Although there may be a shift in the future to include other types of analyses, the analysis technique most frequently used in language research until today is the event-related potential (ERP) technique which will be discussed in the next section.

Event-Related Potentials (ERPs)

As mentioned above, the EEG has been likened to a sound recording of a crowd's roaring during a sporting event. From such a recording, information about, say, when a goal was made, might be possible, but probably not much else. Not much could be said about how the roars were related to particular events during the game.

If, however, one wanted to see if there was a connection between, say, the entrance of a particular player into the game and the crowd noise, one might consider analyzing the sound spectrum of the crowd, exactly when that player entered the game. If the player of interest was particularly popular with women, one might propose that the pitch of the crowd's roar whenever that player entered the game might be higher due to the cries of women. ERPs are a little like that.

Changes in the EEG due to such trivial events as 'seeing an X or an O on the screen' or 'hearing a particular word' are tiny and are generally swamped out by the 'background noise' of the EEG (see Figure 4). If, however, the event is repeated a large number of times (in linguistic research, typically 50–100 times but obviously the more, the better), and the focus of the analysis is on the time window during which the event took place, there is a good chance that one can tease out the response of the EEG at the time the critical stimulus (i.e., the word) was presented. To define the time window, one usually takes the time at which the stimulus is presented and marks it (in EEG jargon, one 'time-locks' the event to the onset of the stimulus) in the EEG recording. To extract the ERP from the background EEG a series of specific analysis steps are necessary, but the most important one is to average across all waveforms at the time of the occurrence of the critical stimulus. An example of a very common ERP experiment is presented in Figure 4. The ERP is that part of the EEG associated with the particular recurring event.

ERPs arising within roughly between 10 and 100 ms after a stimulus (in ERP jargon, 'with a latency of 10–100 ms') are generally considered to reflect early sensory (visual, acoustic, tactile) processes. Longer latency ERPs, i.e., those arising after 100 ms, are usually considered to be associated with perceptual processes and those after 200 ms with cognitive processes such as language or memory.

ERP waveforms are named according to whether the major component is positive ('P') or negative ('N'), according to the length of time they occur after the event, or according to the ordinal position after stimulus onset. One commonly observed ERP is the 'N400' which occurs as a negative ('N') wave roughly 400 ms after onset of the stimulus. Commonly, 'P3' OR 'p300' is the third positive peak arising about 300 ms after the onset of the stimulus. ERP waveforms have meaning, of course, only within the context of the specific experiment in which they are measured.

Advantages and Disadvantages. EEG and ERPs are direct measures of brain activity in the millisecond range. EEG is low-cost, noninvasive, portable and the measurement is silent (a distinct advantage in some linguistic studies). Compared to MEG and fMRI, EEG is generally more movement but its degree of spatial resolution is rather coarse (about 1 cm).

Magnetoencephalography (MEG)

According to Maxwell's Laws, wherever there is a change in an electric field, there is a corresponding change in a magnetic field; 'MEG' is the magnetic correlate to the EEG. (see Figure 5) The MEG is a graph of variations in minute magnetic fields that are measured just above the surface of the scalp and which reflect brain activity. Because the magnetic signals emitted by the brain are extremely weak, an MEG is housed in a specially shielded room so that external magnetic signals, including the earth's magnetic field, cannot interfere. Compared to electric fields, magnetic fields are, however, less prone to distortion due to intervening brain tissue between the source of the magnetic oscillations in the brain and the scalp. MEG thus yields better spatial resolution than does EEG. In comparison to EEG, MEG detects only changes in the components of the field tangential to the detectors, i.e., from the sulci of the brain rather than from both the sulci and the gyri as is the case with EEG. As with EEG, the changes measured by MEG are due to the simultaneous firing of hundreds of thousands of roughly parallel nerve cells.

The detectors of MEG are quite different from the scalp electrodes used for EEG measurement. MEG detectors are called 'squids' (for a superconducting quantum interference device) and are very sensitive instruments used to detect tiny changes in magnetic fields. Rather than have electrodes attached to the scalp, in MEG experiments, the subject sits or lies with the head inside a fixed helmet that contains the squids.

As is the case with EEG, MEG can also be used to detect changes in brain activity in the millisecond range but with a much finer spatial resolution: 0.1–1 cm. And similar to EEG, event-related phenomena can also be obtained by MEG – so-called event-related fields (ERFs). The sources of the neural activity identified with MEG can be projected on to individual brain scans obtained from MRI to visualize the anatomical location of the sources.

Figure 3 The figure depicts the ERPs in response to a go-nogo task. (a) Overlaid voltage distribution of 128 scalp channels. The largest field power occurs at around 360 ms (red box). (b) To reveal the hidden factors (latent variables) accounting for the large field power, an independent component analysis was performed, identifying eight components that account for almost all of the scalp ERP. The last component shown on the right (red box) accounts for nearly all the variance of the nogo P300 as can be seen in the waveform below. (c) On this component (here called IC1) a time-frequency decomposition was performed. This allows us to see when this component has power changes across time and frequency, independent of the phase consistency from trial to trial. This activity can then be examined on single trials to investigate whether there are patterns that show up from trial to trial (not shown here) for specific individuals. (d) To identify the sources of the components (i.e., where in the brain they occur) a dipole model is created from the identified eight independent components. Each dipole has a positive and a negative pole in its electric field. The tail points to the positive pole. The source identified for the (dark green) IC1 component is in the red box. Note how the tail of this component points to the peak positivity at the scalp, represented by the red circular region in the topographical map of IC1 in (b). (e) The Source Information Flow Toolbox analysis allows us to investigate in which way the individual components interact with the other components in different regions of the brain. Each figure corresponds to information flow at a specific point in time, where information flow refers to the Granger causation of one source's activation on another. The numbered dipoles correspond to the components identified. The size of the dipole head (i.e., the round 'node') reflects the strength of the outflow (causal activation coming from this source) and the lines joining the nodes show the end location and asymmetry of the information flow. The more asymmetrical the lines, the more asymmetrical the information flow between the adjoined sources. Figure 4 From EEG to ERP: the oddball paradigm. The oddball paradigm is a very commonly used experiment that reliably produced a specific ERP component, the so-called P3. (a) The subject views the letter X or O presented on a computer screen. Whenever an X or O appears on the screen, a computer program sends this information (via so-called marker codes or triggers) to the program that records the EEG. These can then be 'seen' in the EEG recording. The X is presented more often than the O, here a total of 80 times and the O 20 times, in random order and while the EEG is continuously recorded from a midline parietal electrode site. The recorded signals are filtered and amplified, making it possible to see the EEG waveforms. (b) Based on the marker codes signaling the onset of the stimulus (X or O), the EEG is now segmented into 800 ms time windows (or epochs). This is shown by the rectangles. A great deal of trial-to-trial variability can be seen in the EEG, but experienced viewers can already see a downward (positive) deflection following the infrequent O stimuli. (c) If one now averages across all waveforms in the O time window and all waveforms in the X time window, the P3 component (on the right side) becomes apparent. The P3 is much stronger for the infrequent O compared to the frequent X stimuli. Taken from Steven Luck, 2005. The Event-Related Potential Technique in Neuroscience. MIT Press, Cambridge, MA. (The same Figure was used in Rodden and Stemmer, in Stemmer and Whitaker, 2008. Handbook of the Neuroscience of Language, Elsevier, p. 59.) Legend by B. Stemmer (also in Handbook of the Neuroscience of Language).

Figure 5 MEG machine. The subject lies (as in the image) or sits with the head inside a fixed helmet that contains the superconducting quantum interference device (SQUID).

Advantages and Disadvantages. The major benefits of MEG are its speed (as with EEG in the millisecond range) and its good spatial resolution. The major disadvantages of MEG are price (several million dollars), size (several tons and several scores of cubic meters), and operating/maintenance demands. A further limitation in linguistic studies is its demand for strict head immobility during measurement as well as the exclusion of subjects with any ferromagnetic implants in their bodies.

Investigating Language with the EEG and MEG Techniques

It was previously mentioned that EEG and MEG are particularly suited to study *when* something happens in the brain and *how* linguistic processes unfold over time. There are a number of characteristic brain potentials recorded at the scalp that are assumed to reflect specific neurocognitive processes. These 'ERP components' will be described below.

ERP Responses Reflecting Aspects of Language Processing

An ERP component is usually characterized by the type of stimulus by which it is elicited, its polarity, the time window in which it occurs, and its location (distribution) on the scalp. Note that the location on the scalp is not identical with the source from which the ERP is generated! For example, the highest amplitude of an ERP may have been recorded over electrode F3 ('F' for frontal; uneven numbers refer to the left hemisphere and even numbers to the right hemisphere). This, however, does not mean that the generator of the ERP is in the left frontal cortex. Source localization analyses are used to indicate where the generator is located.

The following ERP responses ('components') are frequently used to address questions of language processing (for details see Steinhauer and Connolly, 2008).

N100. The N100 is a negative component peaking around 100 ms and has classically been associated with physical features such as the loudness of an auditory stimulus or brightness of a visual stimulus. This component has also been considered as a reflection of word segmentation processes.

Figure 6 Phonological mapping negativity (PMN) and semantic N400. MEG responses to words (left) and nonwords (right) for one participant for those left-hemisphere channels showing maximum amplitude for the magnetic PMN (PMNm) and the N400-like response. The corresponding estimates of the PMN- and N400m-like response sources (over a 25-ms time window centered at the peak of the response) are depicted in the brain images. The gray vertical bars indicate the 50-ms time periods within which significant PMNm- and N400m-like responses occurred. Source: Modified after Kujala, A., Alho, K., Service, E., Ilmoniemi, R.J., Connolly, J.F., 2004. Activation in the anterior left auditory cortex associated with phonological analysis of speech input: localization of the phonological mismatch negativity response with MEG. Cognitive Brain Research 21 (1), 106–113. Figure and legend taken from Steinhauer, Connolly, 2008. Event-related potentials in the study of language. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, Elsevier, San Diego.

PMN. The *phonological mapping negativity (PMN)* is elicited when the last word of a sentence violates the contextually developed *phonological* expectation, such as:

The pigs wallowed in the pen (mud).

The PMN occurs after auditory stimuli and is prelexical, i.e., occurs in response to words and nonwords. It peaks in the late 200 ms range (270–310 m) and has a fronto-central scalp distribution. It is assumed that the PMN reflects phoneme awareness and subsequent phonological processing activity (see Figure 6).

MMN. The mismatch negativity (MMN) is elicited by discriminable auditory differences between a frequently occurring 'standard' stimuli and a rare 'deviant' stimulus (the so-called 'oddball paradigm'). The negative component occurs between 150 and 250 ms and shows a frontal scalp distribution (see Figure 7).

N400. The N400 is the first language component that was described (in 1980). It peaks around 400 ms but its latency can range from about 300 to 500 ms. The N400 has a centro-parietal scalp distribution and is slightly right lateralized. The component was first elicited in response to words at the end of a sentence when these words violated the semantic context of the sentence in which they occurred (e.g., *The mother boiled the tires)*. It has been suggested that the N400 amplitude reflects costs of lexical activation and/or semantic integration. The N400 is sensitive to word frequency and it is larger in response to concrete than abstract words (see Figures 8 and 9).

Kutas and Federmeier (2011: 642) summarized the way that ERPs, and the N400 in particular, have been used in 30 years of research as follows:

> 1. ERPs provide temporally exquisite brain measures that have proven especially powerful tools for getting at aspects of cognition largely impenetrable with behavioral measures—for distinguishing among qualitatively different processes and tracking their time courses, often without any overt task and sometimes even in the absence of awareness.
>
> 2. ERP data in general—and the N400 in particular—underscore the crucial role for time (and timing) in comprehension (as in cognition more generally).
>
> 3. Furthermore, N400 data:
>
> (a) point to a distributed, multimodal, bihemispheric comprehension system that is simultaneously open to linguistic and nonlinguistic influences, which often interact;
>
> (b) suggest that access to meaning is a natural part of the stimulus-elicited processing stream, not dependent on an information state such as "recognition," and thus open to all stimuli in all task conditions (unless the feedforward stream has been suppressed by selective attention);
>
> (c) have shown that comprehension is largely nonserial, at least partially incremental, predictive, flexible, and context-dependent; and
>
> (d) have been instrumental in blurring the line between long-honored dichotomies such as prelexical versus postlexical, automatic versus controlled, and literal versus nonliteral processing, among others.

LAN. The left anterior negativities (LANs) are elicited by structural/syntactic violations and have been linked to

Figure 7 The mismatch negativity (MMN) is a preattentive response to discriminate auditory differences between a frequently occurring 'standard' stimulus and a rare 'deviant' stimulus – the so-called oddball paradigm (Näätänen et al., 2001). Panel (a) shows ERPs at midline electrodes for standard stimuli (85%, solid line) and deviant stimuli (15%, dotted line) in an auditory oddball. In panel (b) the difference wave (deviant minus standard) at frontal electrode FZ displays a large MMN and in panel (c) the voltage map between 140 and 190 ms post stimulus onset illustrates the frontal distribution of the MMN (Steinhauer, unpublished data). Within language research the MMN has been used to study categorical phoneme perception, most recently also probing the audio–visual McGurk– MacDonald effect (Massaro, 1998). This effect is achieved by having a subject watch a speaker articulate a syllable that differs from what is recorded on the audio channel the subject hears. The effect occurs when the subject sees the speaker articulate /ka/ but hears /pa/–this combination results in the perception of /ta/. Examination of the McGurk–MacDonald effect has led some researchers to suggest the existence of an 'audio–visual' MMN that has generators different to or overlapping with those that produce the purely acoustic MMN (Colin et al., 2002). They argue that, since their audio–visual stimuli had no acoustic deviants and the visual stimuli per se were incapable of eliciting MMNs, the visual stimuli required an appropriate auditory context within which an MMN was generated to an illusory deviant auditory percept. Also, they suggest that the MMN must result from an automatic, precognitive comparison between phonetic traces held in short-term memory. Figure and legend taken from Steinhauer, Connolly, 2008. Event-related potentials in the study of language. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, Elsevier, San Diego, p. 94.

automatic first pass parsing of a sentence (i.e., automatically analyzing the grammatical relations between words and their hierarchical structure) (e.g., *The child wanted to *car the truck*). The LAN occurs between 100 and 500 ms and shows a left anterior distribution although the distribution is variable (see Figure 10).

A particularly early LAN is only elicited by word category violations and occurs between 100 and 300 ms (*She observed Frank's *on weight lifting sessions)*. However, the functional significance of this component has been seriously questioned by some researchers (Steinhauer and Drury, 2012).

P600. Another component that responds to syntactic violations is the *P600* (also called *syntactic positive shift, SPS*), a positivity that occurs between 500 and 1000 ms and which is distributed over the centro-parietal scalp. It is assumed to reflect relatively controlled attempts to reanalyze and fix the violation. Unlike the LAN, the P600 can be modulated by non-syntactic factors such as processing strategies or experimental tasks (see Figure 10).

CPS. The *closure positive shift (CPS)* is elicited at prosodic boundaries and is assumed to reflect the closure of intonational phrases. This component is among the first brain responses that can be observed in first and second language acquisition (see Figure 11).

In the remainder of this section, we will provide some examples of research questions addressed by the EEG and MEG techniques. It should be pointed out that these illustrations are only a selection of the large number of studies that have used the EEG or MEG method.

As mentioned previously, although the ERP technique is currently the most frequently used approach to address linguistic research questions, other analytical approaches have been developed but have not yet been widely used in language studies.

Brain Oscillations Investigated with EEG and MEG

Rhythmic changes in brain activity can be detected by EEG and MEG and extracted by time-frequency techniques. Combining such techniques with ERP approaches may deepen our insight into language processes in the brain (see also Figure 3 demonstrating the combination of these techniques with the ERP approach).

In language comprehension, our stored knowledge about a word or sentence must be retrieved from memory and integrated with other language input to form an overall representation of the utterance. A large network of widely distributed brain regions is involved in this process. The question how information from these different parts of the brain is integrated or 'unified' is referred to as the 'binding problem.' Assemblies of neurons that fire together simultaneously (i.e., are synchronized) are indicative of linking ('coupling') brain areas into functionally coherent networks. If neural synchronization occurs at a particular frequency, it is assumed that the various components belong to the same functional network. Memory retrieval processes have been related to oscillatory synchrony in the theta frequency range (4–7 Hz) and lexical retrieval processes with synchrony in the alpha frequency range (around 10 Hz); sentence-level semantic unification seems to be reflected in increasing oscillatory synchrony in the gamma frequency range (30–80 Hz), and syntactic unification seems to be reflected by neuronal synchronization in the lower-beta frequency band (13–18 Hz) (for a summary on oscillations in relation to aspects of language comprehension see Bastiaansen and Hagoort, 2006; Bastiaansen et al., 2009; Bastiaansen et al., 2012).

While numerous studies have investigated brain oscillations in language comprehension, applying this technique to language in pathological populations is still rare. An example

Figure 8 ERPs to target words illustrating N400 effects. Negative polarity is plotted upwards. (a) Semantic anomaly in sentences. Semantically implausible content words in sentence contexts elicit larger centro-parietal N400s (dotted lines) than plausible words (solid lines) between 300 and 600 ms. Source: Modified after Steinhauer et al. (2001). (b) PMN and N400 effects in a cross-modal priming study in which written sentences that ended in subordinate words primed superordinate words that ended spoken sentences. Exemplar-subordinate probabilities for congruent endings determined high-constraint primes (shallow end) or a low-constraint primes (sunken ship) which primed auditory target words in the paired sentences (in capitals) that were either congruent (*Pool/Ocean*) or not (*Barn/Marsh*). While incongruent targets (e.g., *Barn/Marsh*) always elicited PMNs and N400s, congruent targets following low-constraint contexts (*Ocean*) yielded PMNs only (L left, R right, M middle, A anterior, C central, P parietal). Source: Modified after D'Arcy, R.C.N., Connolly, J.F., Service, E., Hawco, C.S., Houlihan, M.E., 2004. Separating phonological and semantic processing in auditory sentence processing: a high-resolution event-related brain potential study. Human Brain Mapping 22 (1), 40–51. (c) Source localization revealed distinct neural generators for PMN and N400 components, primarily in the left hemisphere. Figure and legend taken from Steinhauer, Connolly, 2008. Event-related potentials in the study of language. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, Elsevier, San Diego, p. 93.

is a study with dyslexic individuals. Based on the observation that dyslexic individuals exhibit phonological deficits, it has been hypothesized that the timing of auditory processing in these patients is impaired. An MEG study investigated this hypothesis by applying time–frequency analyses to the data obtained from dyslexic individuals. The findings indicated that phonemic processing in the left auditory cortex of dyslexic individuals seemed impaired as reflected in a decreased responsiveness to acoustic modulations at specific frequencies that are optimal for phonemic analysis (30 Hz) (Lehongre et al., 2011).

ERPs in the Study of Figurative Language

The temporal precision of electromagnetic approaches has been exploited to investigate the processes that underlie the interpretation of nonliteral language (e.g., hinting: *I took my car to the garage today* meaning 'Can you give me a lift home?') or figurative language (metaphors, irony, and so on). ERP studies using the N400 have indicated that literal language (*I think that surgeon is a woman*) and figurative language (*I think that surgeon is a butcher*) follow the same time course – thus suggesting that literal and metaphorical types of comprehension do not involve qualitatively distinct processing modes. One ERP study reported that pragmatic cues influenced sentence processing already at a very early stage. These (and similar) findings argue against the views of the standard pragmatic model.

Neuropsychological investigations have indicated a dominant involvement of the right hemisphere in idiom and metaphor processing. Most ERP studies have not supported strict right hemisphere dominance. Joke comprehension, however, seemed more reliant on the right hemisphere than idiom or metaphor processing.

An ERP study on nonliteral language addressing literal statements and indirect requests reported different brain activities for literal statements and indirect requests in response to target sentences that had exactly the same wording but whose interpretation differed depending on the context. The findings suggested greater memory retrieval demands for indirect requests (for a summary of ERP studies of figurative language see Coulson, 2012; Kutas and Federmeier, 2011).

ERPs in Language Development

In the immature brain, the EEG looks different from that of adults. Similarly, ERPs develop as the brain matures and can thus be used to reflect the emergence of cognitive and linguistic development stages (for a summary see Steinhauer and Connolly, 2008; see **Figure 12**).

The MMN can already be identified in newborns thus reflecting their ability to discriminate sounds in their native language from nonnative languages. At around 10 months, the infant shows a specialization for the discrimination of sounds in her/his native language which is reflected in a larger

Figure 9 Over-sentence average ERP to words in written text, including large N400 effect to a semantically anomalous word. Above, on left, is canonical visual ERP comparison of congruent versus anomalous sentence final words, on a 3-μV scale (which applies to all but two waveforms, with 5-μV scales instead); above, on right, is a topographic map of the ERP difference (anomalous minus congruent, N400 effect) from 300 to 500 m postfinal word onset. (*Row 1*) All data sets from central midline site. *Sentence Final:* N400 to semantic anomaly and other sentence endings as a function of average cloze probability (Kutas et al. 1984); *Sentence Medial*: sentence medial noun at three levels of cloze probability; *N400 x Cloze*: correlation between mean N400 (300–500 ms) amplitude and cloze probability (DeLong et al., 2005). (*Row 2) Sentence Reading*: midline parietal ERPs to expected or best completion (BC) ending given sentence context, low cloze probability endings that were and were not related to the BC (Kutas, 1993); *Categorical Relations*: ERPs to sentence final word that is an expected category exemplar or an unexpected, implausible exemplar from the same category as the expected one (related anomalous) or from a different category (unrelated anomalous); *Visual Hemifield:* at the right medial central site in response to final word briefly flashed in the left visual field (LVF) – i.e., initially to the right hemisphere – or right visual field (RVF); *Speech*: at the frontal midline site in response to natural speech (see Federmeier, 2007). (*Row 3*) *Word Association*: ERPs to second word of a word pair, strongly related, moderately related, or unrelated to the first word from same participants as *Sentence Reading* above (Kutas, 1993); *Neighborhood Size*: midline parietal ERP to letter strings including words, pseudowords, and acronyms in a list as a function of orthographic neighborhood size (Laszlo and Federmeier, 2010); *Word Repetition*: ERPs to just the words upon initial presentation and their repetition, from these same experimental runs and participants. (*Row 4*) *Math*: midline central ERPs to correct equation solutions and errors that were or were not related to the solution (Niedeggen et al., 1999); *Video*: midline frontal ERPs to last video frame, congruent or anomalous with prior video context (Sitnikova et al., 2008); *Sentence Repetition*: midline central ERP to congruent or anomalous sentence final words on initial presentation and one repetition. Figure and legend taken from Kutas, M., and Federmeier, K.D., 2011. Thirty years and counting: finding meaning in the N400 component of the event-related brain potential (ERP). Annual Review of Psychology 62, 621–647.

Figure 10 Biphasic LAN and P600 pattern elicited by syntactic word category violations in an English reading study. Negative polarity is plotted upwards. (a) ERP plots of the ungrammatical target words (dotted lines) show a LAN effect between 300 and 500 ms, that is in a similar time interval as the N400, which was followed by a late posterior 600/SPS between 600 and 1000 ms. (b) Voltage maps of the difference waves (violation minus correct control) illustrate the scalp distribution of both ERP components (Steinhauer, unpublished data). Figure and legend taken from Steinhauer, Connolly, 2008. Event-related potentials in the study of language. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, Elsevier, San Diego, p. 97.

and more robust MMN. This discriminatory ability for nonnative sounds decreases and the MMN disappears with age. When infants are able to distinguish prosodic boundaries at around 6–8 months of age, the closure positive shift (CPS) can be identified. Just after infants start to babble, the lexico-semantic N400 can be elicited at around 12–14 months of age. ERP components reflecting syntactic processing (LANs, P600) are the latest to appear. P600 is seen first at around 24 months and LAN at around 32 months. (for summaries of ERPs in the study of language see Steinhauer and Connolly, 2008 and for the N400 see Kutas and Federmeier, 2011).

ERPs in Bilingualism and Second Language Research

The use of EEG to study learning or training programs is still rare and only recently has it begun to be employed. Questions that might be addressed using EEG methods could, for example, relate to beneficial teaching and learning strategies, maturational effects, or influencing variables (cognitive abilities, other language knowledge, cultural background). The question as to whether there is a 'critical/sensitive period' for acquiring a second language has been addressed by several studies. While early ERP studies supported the critical period hypothesis, subsequent studies provided mixed results (for a brief review see Steinhauer and Connolly, 2008).

Most EEG/ERP studies on second language acquisition have been performed outside of formal settings (such as classroom teaching). An important finding has been that ERPs reflecting phonological, semantic, or syntactic processing are modulated by the age at which the language was acquired and the language proficiency of the bilingual individual.

Numerous studies have investigated the 'bilingual advantage' (see Section Investigating Neural Substrates Underlying Bilingualism). Studies using nonimaging methods have reported that bilinguals have an advantage over monolinguals on tasks measuring 'executive functions' (for a summary see Hilchey and Klein, 2011; Kousaie and Phillips, 2012). Executive functions is an umbrella term for cognitive processes that control and manage other cognitive processes or systems such as organizing, planning, attention, working memory, reasoning and problem solving, mental flexibility, as well as initiation, monitoring, and inhibition of actions.

One MEG study reported that despite similar behavioral performance, monolinguals and two bilingual groups differed in activity patterns in specific brain regions (left prefrontal cortex and anterior cingulate cortex) when the groups performed a task that has been related to executive control. Whereas the two bilingual groups activated similar brain regions (compared to the monolingual group), only one of the bilingual groups (Cantonese) outperformed the monolingual group. Questions have been raised as to whether it was the *involvement* of the identified brain regions, or *how* these regions were used that contributed to the general behavioral advantages.

Figure 11 Illustration of the closure positive shift (CPS) at prosodic boundaries of spoken German sentences and a prosody-induced syntax violation negative polarity is plotted upwards. Boundary positions and intonational phrases (IPh) are aligned to the time axis. Sentence A (solid line) has only one prosodic boundary (#) after the verb 'arbeiten,' while B (dotted line) and violation condition C (dashed line) have two such boundaries. At each boundary position a large CPS component was elicited in each condition. Magnitude and slope of the CPS (illustrated by the thick gray line at CPS1) are very similar at all boundary positions. In C, the syntax-prosody mismatch on the verb 'arbeiten' additionally elicited an N400/P600 pattern which superimposes the second CPS. Waveforms represent a grand average ERP at PZ across 40 subjects and approximately 5000 trials per condition. Prosodic boundary information is not only important during language learning but also guides the listener's syntactic analysis and sentence comprehension. Source: Modified after Steinhauer, K., 2003. Electrophysiological correlates of prosody and punctuation. Brain and Language 86, 142–164 and Steinhauer, K., Alter, K., Friederici, A.D., 1999. Brain potentials indicate immediate use of prosodic cues in natural speech processing. Nature Neuroscience 2 (2), 191–196. Translation of sentences: A. Peter promises Anna to work # and to clean the office. B. Peter promises # to support Anna # and to clean the office. C. Peter promises # *[to work Anna] # and to clean the office. (Conditions A and C are lexically identical and differ only prosodically.) Figure and legend taken from Steinhauer, Connolly, 2008. Event-related potentials in the study of language. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, Elsevier, San Diego, p. 100.

The relationship between cognitive control and bilingualism was also investigated with EEG using three different tasks related to various aspects of cognitive control (Stroop, Simon, and Eriksen flanker task). Behavioral measures did not show any bilingual advantage for these tasks. Whereas fMRI studies had shown the activation of similar brain regions in response to the three tasks, ERP responses to the three tasks were different. A comparison of the ERPs of bilinguals and monolinguals demonstrated differences in specific processes related to each task. These differences, however, were not consistent across the three tasks, thus suggesting that bilinguals and monolinguals do not respond uniformly to the tasks (for a summary offv neuroimaging studies investigating bilingualism and second language acquisition see Hilchey and Klein, 2011; Kousaie and Phillips, 2012; van Heuven and Dijkstra, 2010).

Language-Related ERPs in Pathological and Special Populations

ERPs have been used in studies of a large range of pathological conditions and special populations (patients with, for example, aphasia, Alzheimer disease, autism, head injury, dyslexia, mood disorders, schizophrenia, and so on). The focus in these studies has been on cognitive processes and some of the studies have also included investigations of language. The ERPs technique has, for example, been used with aphasic patients to specify impaired language processes, to predict outcome, or to understand how the brain recovers during the acute and chronic stages of aphasia. In dyslexia research, ERPs have been used to try to predict language development in children with a familial risk for dyslexia, or to determine brain responses in brain regions assumed to be implicated in dyslexia. Language-related ERPs have also been used to investigate the states of consciousness in patients in a coma.

Summary of Functional Neuroimaging Techniques Based on Electromagnetism

EEG and MEG are noninvasive techniques that measure electric or magnetic fields, respectively, in the brain. Due to their good temporal resolution in the milliseconds range they are particularly well suited to investigate language processes. With high-density EEG and source localization techniques, a spatial resolution of about 1 cm can be obtained. Scalp-recorded ERPs and ERFs are based on EEG or MEG, respectively, and are assumed to reflect specific neurocognitive processes. A number of ERP responses have been identified and associated with specific language processes. Applying special analysis techniques, the topographical brain sources of an ERP can be identified and its relationship to other brain regions investigated. Another analysis approach makes use of time–frequency analyses to characterize brain oscillations. These have been associated with various aspects of language processing.

The EEG/MEG and ERP/ERF techniques have been applied in a large number of language studies with healthy individuals, individuals with pathological conditions, and special populations.

Functional Neuroimaging Techniques Based on Blood–Brain Interactions

It has been less than 50 years since the first images of localized brain activity associated with brain functions based on blood–brain interactions were taken (for a historical summary see Figure 13). Researchers and lay people alike have embraced these new techniques with enthusiasm (especially PET and fMRI). Reasons are manifold such as the (false) belief of some laypeople that scientists can now watch *what* a person is thinking as witnessed in the vivid and colorful brain images produced by these techniques. Another reason is that these techniques have been used to study the relationship between the 'working' brain and behaviors that are of interest to many people such as sex, emotions, moral values, memory and language, and so on. Some of the philosophical

Figure 12 Emerging ERP components in language development. Adapted from Steinhauer, K., Connolly, J.F., 2008. Event-related potentials in the study of language. In: Stemmer, B., Whitaker, H.A. (Eds.), Handbook of the Neuroscience of Language. Academic Press/Elsevier, San Diego, pp. 91–104.

Figure 13 A chronology of major events associated with the development of human brain imaging with PET and fMR. Taken from Raichle, M.E., 2009. A brief history of human brain mapping. Trends in Neurosciences, 32 (2), 118–126 (Figure 1, p. 119).

pitfalls in these associations were already mentioned in the Introduction. Critical voices have also come from brain scientists calling for a more cautious use of the techniques, with more care being given to the analyses and interpretation of the data. In 2008 a paper from one of the leading fMRI researchers noted that "fundamental questions concerning the interpretation of fMRI data abound, as the conclusions drawn often ignore the actual limitations of the methodology" (Logothetis, 2008). In 2009 a vivid (and probably long overdue) discussion ensued after the publication of two critical papers. A paper entitled 'Voodoo in Social Neuroscience' questioning the reliability of social brain imaging studies circled the internet and caused hot discussions amongst scientists even before it was later published under a different title (Vul et al., 2009). The paper inspired Craig Bennett and colleagues to perform an unusual experiment. The findings were published at the Human Brain Mapping conference in Boston demonstrating *activated* brain regions of a *dead* Atlantic salmon that was scanned with fMRI while (supposedly) performing a decision-making task (see Figure 14).

Every method has its caveats and limitations but within carefully constructed paradigms, applying appropriate analyses, and using wise interpretation, functional neuroimaging techniques can exhibit changes taking place in the brain when cognitive processes such as language are investigated.

Neural correlates of interspecies perspective taking in the post-mortem Atlantic Salmon: An argument for multiple comparisons correction

Craig M. Bennett[1], Abigail A. Baird[2], Michael B. Miller[1], and George L. Wolford[3]

INTRODUCTION

With the extreme dimensionality of functional neuroimaging data comes extreme risk for false positives. Across the 130,000 voxels in a typical fMRI volume the probability of a false positive is almost certain. Correction for multiple comparisons should be completed with these datasets, but is often ignored by investigators. To illustrate the magnitude of the problem we carried out a real experiment that demonstrates the danger of not correcting for chance properly.

METHODS

Subject. One mature Atlantic Salmon (Salmo salar) participated in the fMRI study. The salmon was approximately 18 inches long, weighed 3.8 lbs, and was not alive at the time of scanning.

Task. The task administered to the salmon involved completing an open-ended mentalizing task. The salmon was shown a series of photographs depicting human individuals in social situations with a specified emotional valence. The salmon was asked to determine what emotion the individual in the photo must have been experiencing.

Design. Stimuli were presented in a block design with each photo presented for 10 seconds followed by 12 seconds of rest. A total of 15 photos were displayed. Total scan time was 5.5 minutes.

Preprocessing. Image processing was completed using SPM2. Preprocessing steps for the functional imaging data included a 6-parameter rigid-body affine realignment of the fMRI timeseries, coregistration of the data to a T_1-weighted anatomical image, and 8 mm full-width at half-maximum (FWHM) Gaussian smoothing.

Analysis. Voxelwise statistics on the salmon data were calculated through an ordinary least-squares estimation of the general linear model (GLM). Predictors of the hemodynamic response were modeled by a boxcar function convolved with a canonical hemodynamic response. A temporal high pass filter of 128 seconds was include to account for low frequency drift. No autocorrelation correction was applied.

Voxel Selection. Two methods were used for the correction of multiple comparisons in the fMRI results. The first method controlled the overall false discovery rate (FDR) and was based on a method defined by Benjamini and Hochberg (1995). The second method controlled the overall familywise error rate (FWER) through the use of Gaussian random field theory. This was done using algorithms originally devised by Friston et al. (1994).

DISCUSSION

Can we conclude from this data that the salmon is engaging in the perspective-taking task? Certainly not. What we can determine is that random noise in the EPI timeseries may yield spurious results if multiple comparisons are not controlled for. Adaptive methods for controlling the FDR and FWER are excellent options and are widely available in all major fMRI analysis packages. We argue that relying on standard statistical thresholds ($p < 0.001$) and low minimum cluster sizes ($k > 8$) is an ineffective control for multiple comparisons. We further argue that the vast majority of fMRI studies should be utilizing multiple comparisons correction as standard practice in the computation of their statistics.

GLM RESULTS

A t-contrast was used to test for regions with significant BOLD signal change during the photo condition compared to rest. The parameters for this comparison were $t(131) > 3.15$, p(uncorrected) < 0.001, 3 voxel extent threshold.

Several active voxels were discovered in a cluster located within the salmon's brain cavity (Figure 1, see above). The size of this cluster was 81 mm^3 with a cluster-level significance of $p = 0.001$. Due to the coarse resolution of the echo-planar image acquisition and the relatively small size of the salmon brain further discrimination between brain regions could not be completed. Out of a search volume of 8064 voxels a total of 16 voxels were significant.

Identical t-contrasts controlling the false discovery rate (FDR) and familywise error rate (FWER) were completed. These contrasts indicated no active voxels, even at relaxed statistical thresholds ($p = 0.25$).

VOXELWISE VARIABILITY

To examine the spatial configuration of false positives we completed a variability analysis of the fMRI timeseries. On a voxel-by-voxel basis we calculated the standard deviation of signal values across all 140 volumes.

We observed clustering of highly variable voxels into groups near areas of high voxel signal intensity. Figure 2a shows the mean EPI image for all 140 image volumes. Figure 2b shows the standard deviation values of each voxel. Figure 2c shows thresholded standard deviation values overlaid onto a high-resolution T_1-weighted image.

To

To investigate this effect in greater detail we conducted a Pearson correlation to examine the relationship between the signal in a voxel and its variability. There was a significant positive correlation between the mean voxel value and its variability over time ($r = 0.54$, $p < 0.001$). A scatterplot of mean voxel signal intensity against voxel standard deviation is presented to the right.

Common to all techniques discussed below is that they are based on the assumption that those regions of the brain that are particularly active (say, for example, when judging the grammaticality of a sentence) show an increase in blood flow and energy consumption such as glucose and oxygen. The increase in cerebral blood flow and energy consumption that occurs in specific regions of the brain is then, in some way, measured (albeit differently for all three techniques) and associated with the processes underlying the task (see Figure 15).

As can be seen in Figure 13, PET was invented in 1975 and 7 years later, in 1982, functional imaging with PET and blood flow was introduced. Ten years later, fMRI was first performed in humans. Although today fMRI is the dominant technology used for cognitive studies, the first functional imaging study with language was performed with PET. We will first introduce PET followed by the fMRI and fNIRS techniques.

Positron Emission Tomography (PET)

PET can be used in three different measuring modalities. In one modality, PET can measure pharmaceutical parameters such as the uptake, binding, accumulation, or release of molecules of interest in the brain. These 'binding kinetic studies' are most commonly carried out to determine pharmacological parameters of pharmaceuticals (and their derivatives) such as antidepressants, neurotransmitters, or analogues of neurotransmitters.

Figure 15 Functional brain imaging with PET or fMRI is based on changes in brain circulation and metabolism that are associated with activity changes in both neurons and astrocytes. The profile of these changes was first detailed by PET (a), which showed that activity increases, in this case evoked by stimulation of the visual cortex by a reversing annular checkerboard, consist of increases in blood flow (49%) and glucose utilization (21%) that far exceed that of oxygen utilization (5%) (images adapted from Fox et al., 1988). As a result, the amount of oxygen available in the brain increases (supply increases relative to demand) causing the relative percentage of deoxyhemoglobin (a paramagnetic substance; Box 1) to decrease. The fMRI signal arises because of this change in the relative amount of deoxyhemoglobin (Hb). As shown in part (b), veins containing Hb (dark areas on the upper image) disappear when the animal is breathed on 100% oxygen (lower image) (original experimental data from Ogawa, S. et al. (1990). Brain magnetic resonance imaging with contrast dependent on blood oxygenation. Proceedings of the National Academic of Sciences of the USA 87, 9868–9872. In the human fMRI experiment (c), Hb is decreased because blood flow increases more than oxygen consumption as in part (a) leading to an enhanced signal portrayed here as a localized increase in the fMRI blood oxygen level density (BOLD) signal. Taken from Raichle, M.E., 2009. A brief history of human brain mapping. Trends in Neurosciences 32 (2), 118–126 (Figure 2, p. 120).

In a second modality, PET can be used to measure the regional utilization of glucose (the biochemical 'fuel' of the brain) or to measure regional oxygen consumption as the glucose is metabolized. Most often, studies of glucose metabolism have utilized fluorodeoxyglucose (FDG) labeled with Fluorine-18 as a substance whose accumulation in brain tissue is proportional to glucose metabolism. Such measurement of local brain metabolism by PET takes between 30 minutes and an hour and yields spatial resolutions on the order of 1–3 cm.

In the third modality, information exchange between neurons is indirectly measured by measuring the influx of fresh blood into areas of the brain in which trans-synaptic transmission has taken place. The assumption (which has been largely confirmed) is that, just as in muscle tissue, local areas of the brain that 'work harder' get more fresh blood.

Common to all modalities is the procedure of injecting a radioactive solution into the experimental subject's veins while she/he rests in the narrow PET tunnel which is surrounded by an array of gamma-ray detectors (see Figure 16). As soon as the substance is injected, it is transported by the circulation of the blood throughout the body and its distribution, binding, metabolism, and/or release from locations in the brain can be monitored as the subject performs the experimental tasks.

Advantages and Disadvantages. The advantages of PET lie in its ability to demonstrate the location over time of radioactively tagged molecules in the living human brain. Up to now, this has been used to show regional changes in the metabolism of the brain correlated with linguistically relevant pathologies (aphasias) and with blood-flow changes due to regional neuronal activity in response to linguistic tasks. The spatial resolution of PET is on the order of one half to a few centimeters and the temporal resolution on the order of 1 or 2 min. Compared to fMRI, acoustic the noise of the PET scanner is very low.

The disadvantages of PET are its high cost, its physically invasive nature (the intravenous injection of relatively harmless radioactive compounds), and the demand that the subject's head be immobilized during the experiment. The short time available during which stimuli can be presented (depending on the half-life of the radioactive compound) is a limiting factor for the design of linguistic experiments.

Figure 16 How does PET work? A tracer compound labeled with a positron emitting radionuclide is injected into the participant's circulatory system. She/he is placed within the field of view of an array of detectors capable of registering incident gamma rays. As the radioisotope decays, it emits a positron that subsequently annihilates on contact with an electron. Annihilation leads to liberation of energy in the form of two gamma rays traveling in opposite directions. The gamma rays interact with the scintillating material of the detectors producing a flash of visible light. A photomultiplier tube enhances the scintillations of light so that the signal can be detected. Individual detector units are linked such that two detection events unambiguously occurring within a certain time window may be called 'coincident' and thus be determined to have come from the same radioactive annihilation. Using statistics collected from tens of thousands of coincidence events, a set of simultaneous equations for the total activity of each parcel of tissue can be solved, and a map of radioactivities as a function of location can be plotted. The resulting map shows where the molecular probe has been. Most PET scans in neurolinguistic studies have been 'coregistered' with structural (MRI) scans, to yield the most accurate anatomic information possible. Radionuclides used in PET scanning are typically isotopes with short half-lives such as oxygen-15 (about 2 min). Due to its short half-life, the radionuclides must be produced in a cyclotron which must be not too far away from the PET scanner. The radionuclide is incorporated into compounds normally found in the body such as glucose, water, or ammonia and then injected into the body in order to visualize traces of where they become distributed. The 'neuroimage' is based on an assumption that areas of high radioactivity are associated with brain activity. When oxygen-15 water is used, what is actually measured indirectly is, as is the case with fMRI, the flow of blood – enriched with oxygen-15 containing water – to different parts of the brain. Figure and legend taken from Rodden, Stemmer, 2008. In: Stemmer, Whitaker (Eds.), Handbook of the Neuroscience of Language, p. 63.

Functional Magnetic Resonance Imaging (fMRI)

Similar to PET, fMRI allows three-dimensional representations of locations of altered brain states associated with some task that the brain is carrying out. Another similarity with PET is that identifying brain regions or networks that are involved in a particular task requires comparing the brain activity in response to the particular task (for example, reading words) with one or more baseline/control conditions (for example, the 'resting state'). Inasmuch as it is, however, difficult to control what actually happens 'when the brain is at rest,' the target condition (reading words) can also be compared with a better controlled condition such as reading nonwords. Although this may sound simple, in order to obtain valid results much relies on the ingenuity of the experimenter to find appropriate control conditions and exclude confounding

variables (see Figure 17 for an illustration of an (f)MRI machine).

As previously mentioned, fMRI relies on increased regional blood flow to areas of the brain that are involved in the activity of interest (for example, reading words). Fresh blood carries oxygen bound to hemoglobin, so-called oxyhemoglobin. When the oxygen is extracted from the hemoglobin we talk about deoxyhemoglobin. Due to the increased metabolism in the area of interest, oxygen is extracted resulting in a decrease in oxyhemoglobin and an increase in deoxygenated hemoglobin (deoxyhemoglobin). Things are, however, a bit more complicated. Although deoxyhemoglobin increases, it is proportionally underrepresented. The reason is that more blood than is needed is sent to the area of interest resulting in an oversupply of oxyhemoglobin and thus a decrease in the relative concentration of deoxyhemoglobin per unit volume in the active region. The fMRI signal arises because of this change in the relative amount of deoxyhemoglobin (see Figure 15).

fMRI is not a direct reflection of neuronal activity per se, but rather a reflection of the influx of a particular component of fresh blood (oxyhemoglobin) to sites where nerve cells have very recently fired. The coupling between blood supply and demand in nerve cells is fast but not infinitely fast – it takes time for fresh, oxygenated blood to be re-routed to wash out 'spent blood.'

In fMRI parlance, this indirect but reliable metric of nervous activity is called the 'Blood-Oxygen-Level-Dependent' or 'BOLD' effect. In brief, areas of increases in nervous activity related to changes in brain function can be visualized as areas of increased 'BOLD' activity by the use of fMRI (see Figure 18 for a typical graphical representation of the results of an fMRI experiment).

The images generated are (ideally) depictions of brain activity exclusively associated with some particular cognitive task. This task must be carefully constructed so that it has a distinct beginning and an end. Each task may contain several stimuli such as words. Periods of the target activity (e.g., reading words) are alternated with a control activity (e.g., 'resting condition' or 'reading nonwords condition'). Most commonly, PET experiments use the 'block-design' paradigm whereas fMRI experiments are framed either within the 'block-design' paradigm or the 'event-related' paradigm. Each activity ('block') lasts a fixed amount of time (e.g., 30 s) and is repeated several times. In event-related designs the individual stimuli of the target and the control activity are not summarized in 'blocks,' but each stimulus is presented individually such that the stimuli of the target condition alternate randomly with the control activity. The individual stimuli are presented for a brief period of time such as milliseconds and occur repetitively (see Figure 19).

Figure 17 (f)MRI machine. The radio frequency head coil is being placed on the subject's head. These coils are needed to transmit and receive radio-frequency waves used in MRI scanners. Note that the same machine is used to produce structural (anatomic) MRI and functional MRI (fMRI). Figure courtesy of Siemens Healthcare.

It should be noted that besides BOLD contrast fMRI, there are other forms of fMRI (e.g., arterial spin labeling or blood oxygenation sensitive steady-state) that are, however, rarely used in language research or language rehabilitation and are thus not discussed here.

Advantages and Disadvantages. As with PET, the advantages of fMRI lie in its ability to demonstrate regional nervous activity in the living, behaving human brain. In contrast to PET, fMRI does not require radioactive substances to be injected. The spatial resolution of fMRI is on the order of a few millimeters. Currently, the first machines combing PET and (structural) MRI in *one* machine have become commercially available. They have, however, not been applied to linguistic research yet.

The disadvantages of fMRI are its high cost for the machine (millions of dollars), maintenance, and expert staff, the condition that no magnetically relevant objects are allowed to be present in the subject's body and the demand that the subject's head be rigidly fixed in place during the experiment. fMRI is very loud, which may be a disadvantage for some linguistic experiments. Another disadvantage is its relatively slow temporal resolution on the order of a half second to 5 s.

Diffusion Tensor Imaging (DTI/dMRI) and Tractography

Whereas fMRI allows us to monitor the activity of brain cells, another magnetic resonance imaging technique, diffusion tensor imaging (DTI), provides us with a method to image the fiber tracks/pathways (so-called white matter of the brain) that connect brain cells and through which brain cells communicate. Although a relatively new technique, DTI is rapidly evolving and already a commonly used tool in studies on brain development, disease processes, aging, cognitive neuroscience, and more recently also in language research. DTI provides information on the *structural* (and not necessarily functional) integrity of white matter, and, using tract tracing techniques (tractography), allows one to trace and visualize fiber pathways connecting brain systems. Researchers can thus obtain information on the structural organization of white matter pathways that was previously only possible through brain dissection in the human cadaver. DTI has been used to make brain maps of fiber pathways and investigate their integrity in healthy and patient populations, or correlate them with behavioral and cognitive measures.

DTI measurements depend on the directionally selective (anisotropic) diffusion of water molecules in biological tissues such as fiber tracts. The uninterrupted distance that a water molecule can travel along the length of a nerve fiber is obviously much longer than the distance that it can travel in

Figure 18 Graphical representation of brain activity measured with fMRI. The overall goal of this research was to investigate brain activity in response to stress patterns in German nouns that were manipulated in various ways. In one condition the participants had to read three-syllable German nouns with varying regular stress patterns (e.g., stress on the first, or second, or third syllable). Reading of these stress patterns was compared to 'reading' non-letter signs, the so-called baseline condition. Other comparisons were also performed but are not shown here. The data were analyzed with the Statistical Parametric Mapping (SPM) software, a common tool used in fMRI analysis. One finding easily seen in the brain image was that activation patterns in the left hemisphere were more widely distributed than in the right hemisphere. (a) Top figure on the left: differences in brain activity are represented as if the brain were transparent ('glass brain') in three different cuts (sagital, coronal, horizontal). (b) Top figure on the right: the SPM-design matrix specifies the statistical model for the group of 18 speakers. Each 'box' specifies a stimulus category (nouns with three different stress patterns) for the 18 speakers. (c) Figure at the bottom: the colorful patches represent the location of voxels that have yielded statistically significant differences when contrasting all overt noun productions with regular stress patterns with the baseline condition. The lighter the color, the higher the T value. The analysis is FWE corrected for multiple comparisons at $p < .05$. Figure 19 Block design and event-related design. Schematic representation of a blocked and an event-related paradigm. Block design: periods of task performance (e.g., reading words) are alternated with a control task (e.g., rest), each lasting a fixed amount of time (e.g., 30 s). Event-related design: periods of task performance (e.g., reading movement verbs) are alternated with control tasks (e.g., reading nonwords; reading non-movement words). All stimuli are shown pseudorandomly during a limited amount of time (e.g., 500 ms). Copyright B. Stemmer.

a direction orthogonal to that length and DTI exploits this difference. With DTI, it is possible to measure the diffusion of water molecules along various axes and map regions of the brain and thus determine orientation and properties of nerve fibers.

A technique similar to DTI is 'diffusion-weighted imaging' (DWI). DWI portrays the differential rates of water diffusion in microareas of the brain. DWI is most effective in brain regions in which water molecules can move freely in any direction; such regions are found primarily in the gray matter, ganglia, and brain nuclei. Up to now, DWI has proven most useful in the diagnosis of vascular pathologies of the brain such as those found in stroke patients.

Advantages and Disadvantages. DTI and DWI can be used to uniquely investigate the organization and microstructure of white matter in the healthy brain and they can detect white matter abnormalities caused by disease. DTI has also been used in studies of brain development and maturation.

DTI can only trace the path of white matter tracts but not the direction of signal transduction. Its imaging resolution is about 2 or 3 mm in humans and DTI may thus not 'see' certain white matter tracts. There are also problems related to fibers crossing which DTI may not be able to distinguish (for a more technical description of the method see Mori and Zhang, 2009).

Investigating Speech and Language with PET, fMRI, or DTI

A large number of studies have been published investigating various aspects of speech and language with neuroimaging techniques. In 1988 Petersen et al. (1988) published the first language study using PET. They described brain areas which were active during auditory and visual word processing in healthy subjects and proposed a functional–anatomical model for word processing. These early PET studies had a tremendous impact as they showed that functional imaging could provide information about anatomical locations in relation to behavior in healthy individuals. Until then, researchers had had to rely on studies with brain-damaged patients (so-called brain lesion studies). The first fMRI studies on language were published in 1993 and PET (due to its radioactive component) was pushed into the background. Today, the majority of language studies use the fMRI technique with the number of DTI studies and the combination of the different imaging techniques on the rise. In the following section we will provide examples to illustrate the application of the previously discussed technologies in language research and language rehabilitation.

Investigating Lexico-Semantic Processing

Most functional imaging studies with fMRI have reflected an effort to elucidate the brain regions or networks implicated in specific aspects of language processing in healthy and pathological populations. Early PET and fMRI studies essentially replicated and extended the findings reported by Petersen and colleagues (Petersen et al., 1988; Petersen and Fiez, 1993). Since then the functional-anatomical word processing model has been extended and modified by the large number of neuroimaging studies that followed. What has been accomplished after 20 years of neuroimaging language? Cathy Price at the University College of London has undertaken the enormous task of describing these accomplishments and she has summarized the major findings related to speech, spoken language, and reading at the word level (Price, 2010, 2012; see **Figures 20** and **21**).

When we produce the sounds of speech not only those regions of the brain that are implicated in movement (sensorimotor cortex) become active but also regions that are involved in control and timing processes (such as the anterior cingulate, subcortical areas, and the cerebellum). Hearing sounds and recognizing them as speech has been associated with the left and right superior temporal gyri.

Reading words implicates lexico-semantic processing and a lexico-semantic reading route has been described that involves neural substrates different from those detected in a nonsemantic phonological decoding route. In addition, skilled reading requires the extraction of visual features and thus regions in the occipitotemporal cortex are activated.

When we assign meaning to a word we need to access and retrieve knowledge we have about the world. The neural systems underlying storage and retrieval of semantic knowledge are widespread in the human brain and include large regions of the cortex in the parietal, prefrontal, and subcortical regions of the brain (more specifically, posterior heteromodal assocation cortex, specific subregions of heteromodal prefrontal cortex, and subcortical areas such as medial paralimbic regions) (see **Figure 22**). Heteromodal (also called supramodal) cortex refers to cortex that receives information from several modalities (e.g., visual, auditory, gustatory) and not just a single modality.

Investigating Syntactic Processing

Although it is possible to communicate with single words or utterances only, most of the time we string together words to form sentences and larger text or discourse units. The

Figure 20 Functional model based on neuroimaging studies of language. Figure taken from Price, C.J., 2012. A review and synthesis of the first 20 years of PET and fMRI studies of heard speech, spoken language and reading. Neuroimage 62, 816–847 (figure on p. 820).

question we can thus ask is which brain areas or networks are implicated in sentence processing. Lesion studies have pointed to Broca's area in the inferior frontal gyrus of the left hemisphere. Generally, most neuroimaging studies seem to support this view, however, in a somewhat modified version. Numerous neuroimaging studies have associated syntactically *complex* sentences with regions that include Broca's area but that also extend to regions surrounding the left inferior frontal gyrus. Some studies have suggested that different regions *within* the left inferior frontal gyrus are associated with various aspects of syntactic processing. Other studies have also implicated regions in the left temporal lobe in syntactic processing. Again others have associated bilateral frontal and posterior temporal regions with processes that integrate information into a sentence structure. Due to these generally diverse findings or interpretations, one possibility is that several different and distributed networks are implicated in syntactic processing. Another possibility is that the distributed neural architecture may be obscured by the way neuroimaging data are analyzed. It has, for example, been suggested that instead of relying on group-based analysis methods it may be more beneficial to choose an 'individual-subject's functional localization approach' to account for anatomical variability seen in individual subjects (Fedorenko et al., 2012).

It is noteworthy that the regions related to syntactic processing have also been shown to be activated in other linguistic as well as nonlinguistic cognitive tasks thus raising the question whether or to what degree other cognitive functions overlap with or support linguistic functions.

Another issue that has raised concern is the difficulty of clearly distinguishing syntactic and semantic processing components inasmuch as fMRI studies always contrast different task conditions and at least one of them contains not only structural but also has semantic elements. For example, neuroimaging studies often compare meaningful complex sentences (e.g., *Sophia, who had a broken leg, was given a lift home by Peter*) with syntactically simpler sentences (*He gave her a lift home*) or with nonmeaningful utterances (*Mo soodled lorn en saweek*).

It has been mentioned previously that when assigning meaning to a word the semantic system (also called semantic memory) is activated. The same holds true for comprehending sentences, or, more globally, language. It is assumed that semantic memory stores our abstract, generalized conceptual knowledge without referring to any specific experience. This store is called upon when we try to make sense of words, sentences, or discourse. Generally, fMRI studies comparing brain regions that respond to syntactic tasks with brain regions that respond to semantic tasks showed a large overlap of brain regions that become active during syntactic as well as semantic processing. Functional neuroimaging studies suggest that large areas of the heteromodal association cortex are involved in semantic memory processes and that information is integrated in regions in the temporal and inferior parietal lobes. Another view is that the temporal pole is the principal site of information convergence. (For meta-analyses of neuroimaging studies that investigate language processing see Vigneau et al., 2006, 2011. For a summary on neuroimaging and syntactic processing see Fedorenko et al., 2012. For a summary of the semantic system see Binder et al., 2009; Binder and Desai, 2011).

For a summary on studies investigating language processing in the left and right hemispheres.

Investigating Fiber Tracts Connecting Brain Regions Associated with Language

Until recently, most neuroimaging studies of language have been rather localization oriented and focused on identifying specific brain regions that are activated during task performance. This, however, is only part of the story. Neurons communicate via fiber bundles and to obtain a more complete picture about language processing, it is necessary to identify and elucidate the functional significance of these fiber bundles. Fiber bundles connecting brain regions associated with language were discussed as early as the nineteenth century (for a review see C. Weiller et al., 2009, 2011). A special role was assigned to the arcuate fasciculus, a large fiber bundle running between Broca's and Wernicke's region. Due to advances in MRI technology, fiber bundles can now be made visible by DTI (see **Figures 23** and **24**).

The frontal cortex and the temporal cortex are connected via several fiber bundles. The fiber bundles run in two main

Figure 21 Left hemisphere areas activated by spoken and written language tasks. Left hemisphere areas activated by spoken and written language tasks. Illustrative sketch of the location of language-related activations, based on data from Price et al. This figure was created by overlaying images of activations from many different studies that C.J. Price has coauthored. The colors indicate the type of task or processing that caused the activation. The blue areas are activated by auditory stimuli (auditory 1 followed by auditory 2). The red/brown areas are activated by visual stimuli (visual 1 then visual 2). The orange areas are activated by general action selection (hand or speech). The pink and purple areas are involved in different levels of semantic and syntactic processing depending on the task demands. The dark pink areas are sensitive to the semantic content of the stimuli, the light pink areas are those that are more activated for semantic than for phonological decisions. The light purple areas are activated by spoken and written sentences with the dark purple areas most activated by meaningful and grammatical sentences. The green areas are involved in generating or rehearsing speech. The light green areas are involved in word retrieval; the dark green areas are involved in silent phonological decisions. The khaki green area and PreC/vPM areas are activated by mouth movements during speech. Finally the white areas, corresponding to Broca's area (pOp) and Wernicke's area (pSTS) are involved in both perception and production tasks with familiar stimuli. They may function as convergence zones that receive and send signals to all the other areas involved in perceiving and producing speech. The connections between areas are not shown because we do not yet know enough about how all the areas connect to one another. Figure and legend taken from Price, C.J., 2012. A review and synthesis of the first 20 years of PET and fMRI studies of heard speech, spoken language and reading. Neuroimage 62, 816–847 (figure on p. 821).

pathways relevant for syntactic and semantic processing: the dorsal ('upper') pathway and the ventral ('lower') pathway. The dorsal pathway runs above and the ventral pathway below the Sylvian fissure which separates the frontal from the temporal lobe (see Figure 25).

Two large fiber bundles of the dorsal pathway have been identified that connect the left (posterior) temporal lobe with the left (posterior) frontal lobe: the arcuate fasciculus and the superior longitudinal fasciculus. Various suggestions have been made for the functional significance of the dorsal

Figure 22 Neural substrates underlying semantic processing of words as identified by neuroimaging studies. Meta-analysis of functional imaging studies of semantic processing. This figure displays brain regions reliably activated by general semantic processes, based on reported activation peaks from 120 independent functional imaging studies ($p < .05$ corrected for family-wise error). The analysis method assigns a significance value to the degree of spatial overlap between the reported activation coordinates in a standard volume space. The figure shows selected sagittal sections in the left hemisphere; right hemisphere activations occurred in similar locations but were less extensive. AG = angular gyrus, FG = fusiform gyrus, IFG = inferior frontal gyrus, MTG = middle temporal gyrus, PC = posterior cingulate gyrus, SFG = superior frontal gyrus, SMG = supramarginal gyrus, VMPFC = ventromedial prefrontal cortex. Green lines indicate the *Y*- and *Z*-axes in standard space. Adapted from Binder, J.R. et al. (2009). Where is the semantic system? A critical review and meta-analysis of 120 functional neuroimaging studies. Cerebral Cortex 19, 2767–2796. Taken from Binder et al., 2011. The neurobiology of semantic memory. Trends in Cognitive Sciences 15 (11), 530.

Figure 23 Tractography reconstruction of the arcuate fasciculus using the two region of interest approach. Broca's and Wernicke' territories are connected through direct and indirect pathways in the average brain. The direct pathway (long segment shown in red) runs medially and corresponds to classical descriptions of the arcuate fasciculus. The indirect pathway runs laterally and is composed of an anterior segment (green) connecting the inferior parietal cortex (Geschwind's territory) and Broca's territory and a posterior segment (yellow) connecting Geschwind's and Wernicke's territories. Figure and legend taken from Catani, M., Jones, D.K., ffytche, D.H., 2005. Perisylvian language networks of the human brain. Annals of Neurology 57 (1), 8–16 (Figure 3, page 11).

pathway: mapping sound onto articulatory based representations, being implicated in speech repetition, processing complex syntactic operations, and serving higher-level semantic and language function. Ventral pathways connect the left temporal cortex with the left prefrontal cortex via the extreme fiber capsule system (also called the inferior fronto-occipital fasciculus) and the uncinate fasciculus. It has been suggested that these pathways support the mapping of sound to meaning, the acquisition of natural grammar, and syntactic processing; the uncinate fasciculus has especially been related to semantic processing. Another left lateralized pathway connects posterior Broca's region with areas in the medial frontal cortex (presupplementary motor area): the frontal aslant tract. Alterations in the aslant tract, the uncinate fasciculus, and the arcuate fasciculus have been described in patients suffering from primary progressive aphasia, a progressive breakdown of language functions. In these patients semantic impairment was correlated with degeneration of the uncinate fasciculus, grammar deficits with degeneration of the arcuate fasciculus, and deficits in verbal fluency with the frontal aslant tract, thus suggesting a link between these fiber tracts and the observed language behavior (M. Catani et al., 2013) (for details on language-relevant fiber bundles see Catani et al., 2005, 2013; Catani and Mesulam, 2008; Friederici and Gierhan, 2013; Hickok and Poeppel, 2004; Saur et al., 2008; Weiller et al., 2009).

Figure 24 Tractography reconstructions of the direct and indirect pathways in six individual subjects superimposed on sagittal fractional anisotropy data. The three segments are color coded using the conventions of **Figure 23**. Both direct and indirect pathways are present in each subject, but an intersubject variance is evident. Figure and legend taken from Catani, M., Jones, D.K., ffytche, D.H., 2005. Perisylvian language networks of the human brain. Annals of Neurology 57 (1), 8–16 (Figure 4, p. 12).

The Default Language Network

Numerous fMRI studies using tasks targeting similar language functions at the word or sentence level have reported activation in similar brain regions. These brain regions have been referred to as the default language network. It is important to note that the default language network is not very well defined and represents only a rough approximation at a very general level of the neural substrates implicated in word- and sentence-level processing. Note that not all researchers adhere to the view that such a default network exists.

In infants as young as 2 days old the language-related neural substrates are already fully active in both hemispheres although they are still functionally and structurally immature (Perani, 2012). By the age of 6, maturation processes still continue as shown with a functional connectivity MRI approach (i.e., analyzing low-frequency fluctuations) that examined the default language network underlying sentence processing in adults and children (Friederici, 2011). In adults, the default language network showed a strong connectivity *within* one hemisphere, i.e., between left frontal and left temporal language regions. These connectivity patterns were not seen at the age of 6 years in children, although, by that age, the classical language regions are functional. Instead, children showed a strong functional connectivity *between* the hemispheres (especially between superior temporal regions). These findings suggest that the default language network differs in adults and children of this age. An alternative interpretation would be that the default language network does not yet exist in children.

Figure 25 Language-relevant brain regions and fiber tracts (schematic and condensed view of the left hemisphere). The dorsal pathway connecting dorsal premotor with posterior temporal cortex (pMTG/STG) involves the superior longitudinal fasciculus (SLF) III and/or the SLF II and the SLF-temporo-parietal; the dorsal pathway connecting BA 44 with the posterior STG involves the AF. The ventral pathway connecting the frontal cortex (FC), that is, BA 45 and others, with the temporal (TC), the parietal (PC), and the occipital (OC) cortex, involves the IFOF (also called the ECFS); the ventral pathway connecting the anterior inferior FC (aIFC), that is, BA 47 and others, and the FOP, with the anterior TC (aTC), involves the uncinate fasciculus (UF). Figure and legend taken from Friederici, Gierhan, 2013. The language network. Current Opinion in Neurobiology 23, 250–254 (Figure 1, p. 251).

Investigating Neural Systems Underlying Linguistic Pragmatic Behavior

Linguistic pragmatics views language as action – interpreting utterances, texts, and discourse through its use in context. Considering that linguistic pragmatic behavior operates on words, it is not surprising that language networks active at the word and sentence level (possibly the default language network) are implicated. The question is, thus, whether pragmatics relies on these networks alone, or whether additional networks are implicated.

A meta-analysis of fMRI studies addressing text comprehension reported activation of brain regions that are typical for the default language network (e.g., left inferior frontal regions, anterior temporal lobe in both hemispheres, and left-dominant middle and posterior temporal regions). In addition, regions outside but still adjacent to the default network were activated and were termed the 'extended' language network (Ferstl, 2010; Ferstl et al., 2008). There is currently no agreement amongst researchers on the specific function of these 'extended' networks.

The situation is similarly unclear concerning the neural substrates underlying figurative language such as metaphors, idioms, irony, or sarcasm. Studies with patients who had damage to the right hemisphere and showed problems with figurative language gave rise to the classical right hemisphere hypothesis that stated that figurative language is processed in the right hemisphere. There is currently little evidence from fMRI studies supporting this hypothesis. What seems to emerge is that properties of the figurative language concept such as degree of figurativeness, familiarity, conventionality, as well as cognitive processing difficulty may determine the degree to which the right hemisphere is implicated, with cognitive processing difficulty possibly playing a particular role. Cognitive and psycholinguistic approaches have grounded figurative language in bodily experience and linked them to the sensory–motor system. The very few fMRI studies that have addressed this issue seem to support the idea, at least when the concepts investigated contain some sort of action components.

Finally, it has been suggested that pragmatics is an emergent phenomenon and – apart from the default language network – the neural substrates implicated may be determined newly every time figurative language occurs. This may happen because of the specific characteristics of the figurative language concept, the cognitive systems, mental state and experience specific to the individual, the environment in which these concepts occur, and the way these variables are weighted (for a summary on neuroimaging studies of pragmatics see Stemmer, 2008, 2013).

Investigating Neural Substrates Underlying Bilingualism

The question of how language is processed in people who master more than one language has raised considerable interest not only in academics but also in the general population and at a political level.

Due to the constraints of the imaging methods, studies in bilingualism usually use different experimental designs than behavioral methods thus making comparisons difficult. It has also repeatedly been pointed out that it is difficult to obtain a clear picture inasmuch as not all studies control important variables, or they are heterogeneous in those

variables such as age of acquisition of a second language; proficiency in the language; frequency and context of use of the language; and stimuli, tasks, and experimental design. These limitations should be kept in mind during the following discussion.

Numerous studies have addressed the question of whether the first and second language are structurally represented or functionally processed similarly or differently in the brain. The picture that emerges is heterogeneous. Some studies reported that brain regions activated by two or more languages overlapped while others reported that language tasks in bilinguals activated different or partially different brain regions. One meta-analysis of 24 fMRI studies with bilinguals reported stronger activation and recruitment of common first/second language regions during the processing of a second language when the second language was learned later in life, or second language proficiency was low, or the frequency of exposure was low (Indefrey, 2006).

Several fMRI studies have addressed the question of whether bilinguals have an advantage over monolinguals on tasks measuring executive functions (see Section ERPs in Bilingualism and Second Language Research).

An fMRI study comparing mono- and bilinguals reported that despite similar behavioral performance, bilinguals and monolinguals exhibited activity in different brain regions in tasks that required selecting a response and suppressing interfering material (Flanker task and No-go tasks) (Luk et al., 2010). The same brain regions were, however, recruited by both language groups when a response had to be inhibited. The findings were interpreted as indicating that bilingualism modified the neural networks responsible for achieving effective general cognitive control of nonverbal stimuli. Other fMRI studies reported better adaptation to the conflict task by bilinguals compared to monolinguals and associated this with less activity in a specific brain region (anterior cingulate cortex). fMRI studies investigating whether bilinguals have an advantage switching from one task to another reported that monolinguals demonstrated a switch cost (reflected as an increase in reaction time). Monolinguals and bilinguals differed in the recruitment of brain regions in response to the switch and nonswitch tasks. A task-switching paradigm was also used in a recent fMRI study that addressed the question of whether lifelong bilingualism offsets age-related declines in neural efficiency for cognitive control processes (Gold et al., 2013). Behavioral data showed that older adult bilinguals switched faster between perceptual tasks than monolinguals. The fMRI data revealed that compared to monolinguals, bilingual older adults outperformed the monolingual peers while showing a decrease in activation in the left lateral frontal and the cingulate cortex. This was interpreted as suggesting that lifelong bilingualism offsets age-related declines in neural efficiency during specific cognitive control processes (for a summary on neuroimaging studies investigating bilingualism and second language acquisition see, for example, Bialystok et al., 2012; Hilchey and Klein, 2011; Indefrey, 2006; Kousaie and Phillips, 2012; van Heuven and Dijkstra, 2010).

For a discussion of language dominance in each hemisphere (*see* Lateralization of Language as Demonstrated by Brain Imaging Procedures).

Generally, the few fMRI studies that have been carried out show that neuroimaging may reveal differences in response to cognitive control tasks that are not apparent in behavioral measures. Further, it seems that fMRI data support behavioral findings that describe a bilingual advantage for cognitive control. Similar to the MEG study reported in the Section ERPs in Bilingualism and Second Language Research, however, one may ask whether the mere findings of some studies that functionally distinct brain regions were involved in the task performance of bilinguals compared to monolinguals justifies the interpretation that these regions are associated with inhibitory control and are responsible for the bilingual advantage.

Investigating the Neurochemical Bases of Speech Production

The findings reported in the previous sections have used PET, fMRI (including special analysis techniques to obtain functional connectivity patterns), or DTI methods. Language studies that combine various techniques (such as fMRI and EEG) are on the rise although 'combining techniques' does not necessarily mean simultaneous application of the methods. A combination that has been used less frequently is fMRI and PET possibly due to the high costs and logistics involved. One study combining PET, fMRI, and DTI techniques investigated the relationship between speech production and dopamine release in healthy subjects (Simonyan et al., 2013). Investigating the neurotransmitter dopamine during speech production was motivated by the clinical observation that alterations in the dopamine system may lead to speech and language impairments (e.g., inability to control motor aspects of speech production; difficulties with phonological and syntactic processing; and so on). Data were acquired in separate PET and fMRI sessions while subjects listened to grammatically correct sentences or while they were resting. PET was used with a dopamine receptor radioligand to study dopamine release. fMRI was used to investigate activity patterns in a specific subcortical brain region (the striatum which is known to be implicated in movement control) and to study functional connectivity patterns. DTI was obtained to examine the structural network organization in the striatum. The authors reported predominantly left lateralized dopamine release within specific regions of the striatum during sentence production. Dopamine release seemed to influence the lateralization of functional speech networks but not of structural speech networks.

Although the study has limitations (e.g., choice of stimuli and experimental conditions: speech versus resting state; separate PET and fMRI sessions; method of analyses), the study nevertheless demonstrates what is currently possible. In this context it is noteworthy to mention that the first 'all-in-one' PET-(f)MRI machines are now commercially available.

Language Rehabilitation and Recovery

An important issue in language rehabilitation concerns the cerebral structures or networks implicated in recovery of function such as in individuals suffering from aphasia. Brain repair and reorganization depend, at least in part, on the site and extent of the brain lesion, and the recruitability of the partially

Figure 26 Dissociated performance on repetition performance of nonwords in chronic aphasia according to the site and extent of structural damage. (a) MRI of a patient with chronic nonfluent aphasia and *impaired* repetition (Broca's aphasia). A large area of infarction is seen involving the left frontotemporal cortex with extension into insula, basal ganglia (white arrows), and different segments of dorsal (arcuate fasciculus) (green arrow) and ventral pathways (blue arrows) crucial for language repetition. Despite significant bilateral activation of temporal and frontal lobes and supplementary motor areas on fMRI during nonword repetition, the patient's performance on this task was severely impaired (27/104). (b) Schematic diagram depicting the area of infarction (gray triangle) which involves both the dorsal (green) and ventral (blue) pathways underlying language repetition. (c) MRI of a patient with chronic nonfluent aphasia and *preserved* repetition (transcortical motor aphasia). A large area of infarction is seen on the left mesial frontal cortex (white arrows) with minimal compromise of the anterior portion of the dorsal pathway (green arrow). Patient's performance on nonword repetition was preserved (95/104) and the fMRI during nonword repetition shows significant activation of a bilateral phonological language network similar to the one activated in normal control subjects. (d) Schematic diagram depicting the area of infarction (gray triangle) which minimally involves the anterior part of the dorsal pathway (green) with sparing of the ventral pathway (blue). The left side is represented on the left side of the MRI. Figure and legend taken from Berthier M.L., García-Casares N., Walsh S.F., Nabrozidis A., Ruíz de Mier R.J., Green C., Dávila G., Gutiérrez A., Pulvermüller, F., 2011. Recovery from post-stroke aphasia: lessons from brain imaging and implications for rehabilitation and biological treatments. Discovery Medicine 12 (65), 275–289.

damaged and nondamaged structures to contribute to language processing (see Figure 26).

fMRI has been used to identify neural activity patterns that allow predictions about the recovery process. In individual patients it has been shown that increased activation foci in the intact right hemisphere during language task performance very early after the stroke predicted favorable long-term outcomes. As most studies rely on a small sample size, an international database is currently collecting recovery patterns of poststroke aphasic patients with the objective of allowing outcome prediction based on a large database.

Only few studies have used MRI/fMRI or DWI to predict the degree of recovery in the very early *acute* stage poststroke. These studies suggest that recovery of language function depends on three basic mechanisms: (1) reperfusion of incompletely damaged tissue around the lesion (perilesional); (2) resolution of edema at the site of the lesion and improvement of reduced metabolism in regions distant from the site of the lesion, and (3) reorganization of the relationship between structure and function (Berthier et al., 2011).

Most brain imaging studies have investigated the neural processes underlying recovery from *chronic* poststroke aphasia. Late recovery mechanisms seem to rely on compensation (i.e., recruitment of additional brain areas) and reorganization (i.e., displacement of a primary language area). The potential capability of the brain to compensate for lesions has been referred to as 'neural plasticity.'

The role of the right (nondamaged) hemisphere in the recovery process is still a debated issue. While some have reported that both hemispheres contribute to network reorganization in chronic poststroke aphasia (Turkeltaub et al., 2012), others have associated better recovery and less right hemisphere involvement with small- and medium-sized lesions in the left hemisphere (Berthier et al., 2011). An increase in right hemisphere activity during language tasks as measured by PET or fMRI has been viewed as maladaptive and impeding recovery, or as reflecting other cognitive strategies, or as inhibitory on the remaining left hemisphere functions.

fMRI has also been used to study the effect of medication in chronic poststroke aphasia. Treatment-induced decreased

activity in fMRI, for example, was interpreted as reflecting decreased effort and more efficient processing of the task. (For a summary on the role of the two hemispheres in the recovery process of aphasic patients; for a summary on neuroimaging studies in language rehabilitation see Berthier et al., 2011; Meinzer et al., 2011; Turkeltaub et al., 2011.)

Functional Near-Infrared Spectroscopy

The pioneering work on the application of near-infrared spectroscopy (NIRS; formerly known as diffuse optical imaging) in humans goes back to 1977. While the early systems were confined to using a single channel (i.e., one near-infrared source and one detector), by the mid-1990s multichannel NIRS systems were available thus making it possible to explore the 'functional' working of the brain with NIRS – hence the name 'fNIRS.' Unlike methods such as PET or fMRI, NIRS is better suited to simultaneously provide information about the source of neural activity (*where* something happens) as well as its time course (*when* something happens). fNIRS measurements have been shown to be highly consistent with fMRI findings and fNIRS results have been reproduced reliably over time (for a summary and history of NIRS see Ferrari and Quaresima, 2012).

Amazing but true – simply by shining light on the surface of the brain and by recording and analyzing the reflected light patterns one can obtain maps of the functional architecture of the brain. Similar to other hemodynamic techniques (PET, fMRI), fNIRS depends on the assumption that those regions of the brain that are particularly active demand more freshly oxygenated blood than the surrounding brain tissue. Hence, oxygenated blood (more precisely hemoglobin in the red blood cells carrying oxygen) rushes to the areas associated with the task where the oxygen is used. While there is consensus that the concentration of oxygenated blood (HbO_2) can be viewed as an indicator of brain activity in fNIRS, there is an on-going discussion over which of the parameters, HbO_2, total hemoglobin (HBT), or deoxygenated hemoglobin (HbR), reflects activation best.

When shining light of an appropriate wavelength (in this case infrared light) on the head, this light penetrates tissues and bone and is absorbed by hemoglobin to various degrees. Light reflected after this absorption is measured by a set of probes (near-IR emitters and detectors) that are attached on the scalp (see **Figure 27**), and from these measurements changes in the brain's activity can be estimated. In more sophisticated terms, as a light source NIRS uses the wavelengths of light in the near-infrared range (700–1000 nm) to measure changes in the brain's oxygen absorption based on optical properties of hemoglobin (see **Figures 28** and **29**). Although there are three different types of NIRS techniques, the one that has been used in nearly all language studies is the continuous wave technique which simply measures the attenuation of light through the head. An important feature of NIRS not shared by fMRI is the capability to rapidly and *simultaneously* measure changes in local cerebral blood volume, and concentrations of hemoglobin carrying oxygen (oxyhemoglobin) and deoxygenized hemoglobin. fMRI provides a combined blood oxygen level density (BOLD) measure (that is, a ratio between oxygenated and deoxygenated hemoglobin).

Advantages and Disadvantages. NIRS is noninvasive, silent, low cost, and (depending on the number of channels) light weight and portable. It can be used with infants, children, and adults. NIRS is also relatively movement tolerant, and, compared to MEG, fMRI, or PET, the participant is more mobile and not confined to a narrow space. The main disadvantage of NIRS is the spatial resolution. Because of the nature of scattered light, the penetration depth of NRIS is limited to about 3 cm deep into the head (and 1–1.5 cm into the cortex) depending on the distance between IR emitters and detectors. The spatial resolution thus decreases with increasing depth and deep brain structures cannot be measured. Temporal resolution is good but lower than that of EEG. Another disadvantage is the difficulty of separating the NIRS signal of interest from interfering signals from other cerebral tissue. Further disadvantages are that near-infrared light is attenuated by dark hair color and that the placement of the array of optical fibers is complicated and time consuming. Furthermore, the optical fibers cannot cover the entire surface of the brain thus making it impossible to explore all possible neural

Figure 27 An example of functional near-infrared spectroscopy measurements over the human head. The illuminating optic fiber bundles (sources) and the collecting ones (detectors) are assembled into a flexible probe holder ensuring that the 4-cm distance, relative to each other, is fixed. The probe holder is positioned over the left hemisphere using the 10–20 frontal and temporal coordinates (International 10–20 system). The probe holder is fixed to the head by a velcro brand fastener, adapting it to the size and shape of the head. The probe holder and its position on the head allow the creation of a stable optical contact with the scalp for all optic fiber bundles. Figure and legend taken from Quaresima, V., Bisconti, S., Ferrari, M., 2012. A brief review on the use of functional near-infrared spectroscopy (fNIRS) for language imaging studies in human newborns and adults. Brain and Language 121 (2), 79–89.

Figure 28 Principles of noninvasive optical imaging: optical probes are fixed to the head defining the sampling volume (pink ellipse). Measuring changes in attenuation at two or more wavelengths allows us to calculate changes in the concentration of HbO and HbR. An increase in HbO and/or a decrease in HbR indicate cerebral activation. Physiologically this pattern results from an increase in regional cerebral blood flow (rCBF) consisting of an increase in blood flow velocity (rCBFv) and volume (rCBV). The increase in rCBF overcompensates the demand in oxygen (Fox and Raichle, 1986). An increased 'washout' of HbR results from increased rCBFv. This decrease in HbR is the major source of fMRI BOLD-contrast increases (Steinbrink et al., 2006). The change in total hemoglobin concentration (HbT = HbR + HbO) correlates with blood volume (CBV), which can be assessed by PET. Notably the assessment of electrophysiological markers of activation by EEG or MEG (right side of graph) is undemanding. Figure and legend taken from Obrig, H., Rossi, S., Telkemeyer, S., Wartenburger, I., 2010. From acoustic segmentation to language processing: evidence from optical imaging. Frontiers in Neuroenergetics 2 (13), 1–12 (Figure 1, p. 3).

systems in an experiment. (for summaries of the method see Aslin and Mehler, 2005; Ferrari and Quaresima, 2012; Gervain et al., 2011; Quaresima et al., 2012).

fNIRS Application to Language Studies

Nearly all language studies with fNIRS have targeted the brain's classical language areas. About one-third of currently published studies have investigated newborns and infants addressing topics such as the development of language lateralization, prosodic processing, or structural properties of language.

fNIRS studies with newborns and infants. The first study to show that aspects of language are lateralized to the left hemisphere already in newborns used fNIRS. Left temporal brain regions showed increased activation when newborns listened to speech stimuli played forward but not when they were played backwards. Individual acoustic/phonological properties, however, seem to lateralize later as Japanese infants have shown left lateralization adult patterns for individual acoustic/phonological properties only after 25–28 months of age.

fNIRS studies have also addressed the development of prosodic processing. Generally, however, these data are difficult to reconcile. The findings indicated that prosodic information is used at an early age by infants, possibly as of 3 months, and it seems that there is a tendency for a stronger response in the right hemisphere (although not all studies have found a lateralization effect). For example, increased activation in frontal brain regions of both hemispheres (thus no lateralization) was reported in response to normally intonated prosody but not to monotonous speech with flat prosody in Japanese newborns. At 3 months, lateralization to the right hemisphere (temporoparietal brain area) was observed with greater activation in response to normally intonated speech as compared to flattened prosody. These findings were interpreted as indicating that over-development prosody is initially processed only acoustically (and not linguistically). Later in development, at 10 months, the frontal regions on both sides in addition to left temporal and temporoparietal regions were more activated in response to flattened than to normal speech. The latter findings are somewhat difficult to interpret. One suggestion was that it reflects the *effortful* attempt to integrate not-normal, flattened speech into the linguistic system thus activating larger language-associated regions. Other studies have observed that the inferior frontal cortex in the right hemisphere seemed to be associated with emotional prosody already in infancy while regions in the left temporal hemisphere seemed to process voices very early in development.

At birth infants are able to distinguish phonemes of a wide range of languages. During the process of native language acquisition, this broad discrimination ability is lost. Using fNIRS phonetic processing was investigated in two groups of bilingual and monolingual babies, that is babies younger than 4–6 months and older than 10–12 months. In both groups, regions in the left temporal brain (superior temporal gyrus) for phonetic processing and regions in the left frontal brain (left inferior frontal cortex) for meaning retrieval and syntactic and phonological patterning were implicated. In the latter case, activation became stronger the older the babies. It was also observed that older bilingual babies were still sensitive to nonnative phonetic contrasts when monolingual babies could no longer make these distinctions (Petitto et al., 2012; see **Figure 30**).

Different languages have different combinatorial rules for phonemes in their language, so-called phonotactic rules. For example /fl/ is a possible combination at the onset of English words (*flight*) while /tl/ is not. Studies using fNIRS

Figure 29 Examples of optical imaging results in infants and neonates. (a–c) Time courses of HbO and HbR in three different age groups. Note that the response pattern is similar in all three studies though magnitude differs. (a) Neonates' response to structured noise. Here the statistics on HbR↓ yielded a lateralized response (adapted with permission from Telkemeyer et al., 2009). (b) Response to sentences in 10-month-old infants. In this study HbO↑ yielded the effects shown in (d) (adapted with permission from Homae et al., 2007). (c) Response to hummed sentences in 4-year-old children. HbO↑ *and* HbR↓ showed statistically significant results (adapted with permission from Wartenburger et al., 2007). (d) Topographical information is available when using probe arrays (24 volumes over each hemisphere; adapted with permission from Homae et al., 2007). The results show the differential activation to normal vs. flattened speech in two age groups (10 and 3 months). Note that the lateralization changes sides (red: larger response amplitude for flattened speech than normal speech; blue: normal > flattened; results are based on HbO↑). (e) Simultaneous assessment of EEG and optical imaging in a neonate as used in (Telkemeyer et al., 2009). (Permission from the infant's parents to show the picture was obtained.) Figure and legend taken from Obrig, H., Rossi, S., Telkemeyer, S., Wartenburger, I., 2010. From acoustic segmentation to language processing: evidence from optical imaging. Frontiers in Neuroenergetics 2 (13), 1–12 (Figure 2, p. 4).

with infants have reported that phonotactic rules seem to operate already in infants as of the age of 3 months without clear lateralization patterns.

Another question addressed with NIRS was when newborns begin to process the structural properties of language. It was observed, for example, that newborns reacted with increased neural activity in the temporal regions of both hemispheres (with left temporal more pronounced than right temporal) and in left frontal areas when listening to speech that followed a structural rule as compared to unstructured speech. This seems to indicate that newborns are sensitive to structural patterns as of very early on.

Other rare applications of fNIRS have been to investigate language in epileptic children, in children with autism and in deaf children.

Generally, with regard to fNIRS studies with infants and children, concern has been expressed that the fNIRS findings in children may need to be interpreted differently from those of adults inasmuch as the infant brain is still immature. Vascular regulation is different from the adult brain and light scattering and absorption may also differ in the immature brain. (For a summary of language studies in infants and children see Dieler et al., 2012; Gervain et al., 2011; Obrig et al., 2010; Quaresima et al., 2012.)

fNIRS studies with adults. Numerous fNIRS studies have been performed with adults addressing topics such as language lateralization , syntactic processing, semantic processing, reading, or language organization in bilinguals. Generally, most fNIRS studies have corroborated and, to some extent, expanded findings from previous imaging studies with other techniques. There are, however, also inconsistencies with other brain imaging studies.

For example, an fNIRS study that investigated syntax processing reported involvement of the left inferior frontal gyrus (a region containing Broca's area) when participants had to judge whether a sentence was syntactically correct. Another study suggested that, in native Japanese subjects, phoneme discrimination was associated with hemodynamic changes of the left hemisphere. Several non-fNIRS neuroimaging studies, however, have shown that intonational pitch is usually processed in the right hemisphere. When, however, intonational pitch is used to discriminate words, as

Figure 30 Average difference between standard and target peak activations for bilingual and monolingual babies by age in the left inferior frontal cortex (IFC) and left superior temporal gyrus (STG) for the native and nonnative language conditions. Note that the bilingual and monolingual babies show different patterns of activation in the left IFC. The bilingual babies had more similar activity levels for the native and nonnative phonetic contrasts than the monolingual babies, who showed greater left IFC activations to their native language and this corresponds to behavioral data showing that older bilingual babies' phonetic discrimination capacities remain 'open' at the time when older monolingual babies' phonetic discrimination capacities 'close' to only their native language phonetic contrasts. Figure and legend taken from Petitto, L.A., Berens, M.S., Kovelman, I., Dubins, M.H., Jasinska, K., Shalinsky, M., 2012. The 'Perceptual Wedge Hypothesis' as the basis for bilingual babies' phonetic processing advantage: new insights from fNIRS brain imaging. Brain and Language 121 (2) 130–143 (Figure 4, p. 138).

in Japanese, left frontal regions were activated in fNIRS studies.

An early PET study had indicated that listening to continuous speech activates regions in the left temporal lobe, a finding that was later also supported by an fNIRS study. A few studies have investigated word processing in adults. One study implicated the left inferior frontal brain regions with the statistical segmentation of tone sequences and this has been viewed as the basis of segmenting sentences into meaningful words.

Several studies have reported increased activity in Broca's and Wernicke's area in response to reading tasks.

Overt speech studies pose a problem for fMRI due to the noise of the MRI scanner as well as to the head and jaw movement artifacts during the task. fNIRS is better suited for these types of experiments and were used during face-to-face conversation in which topic and conversation time were predefined. Compared to reciting syllables, during conversation periods an increase in oxyhemoglobin and a decrease in deoxyhemoglobin were observed in frontal and temporal regions (Suda et al., 2010). It might be mentioned that the control condition (reciting syllables) may not have been an optimal choice against which to compare conversation.

Verbal fluency tasks reflecting lexical retrieval processes are a common task used in imaging and nonimaging methods. Numerous fNIRS studies have used these tasks (such as naming words beginning with a certain letter, i.e., phonological fluency, or naming animals, i.e., semantic fluency) and most have reported increases in oxyhemoglobin over bilateral frontal and temporal brain regions and a simultaneous decrease of deoxyhemoglobin. tDCS studies (see Section Transcranial Direct Current Stimulation), however, have suggested left lateralization for these tasks. It should be noted

that some fNIRS studies using verbal fluency tasks showed methodological flaws, which may have influenced the results and their interpretation. In addition, while the reliability of the fNIRS results for verbal fluency tasks has been established at the group level, some researchers have questioned its reliability at the single subject level.

fNIRS has been compared with the intracarotid amobarbital test (Wada test) which has been the gold standard to determine presurgically in which hemisphere language is predominantly represented. Results of tests relying on fNIRS have shown a good correlation with the Wada test concerning the prediction of language dominance. As mentioned previously, however, inasmuch as fNIRS may not be reliable at the single subject level it is not suitable as an alternative to the Wada test. While fNIRS may be a potential candidate to replace the Wada procedure, hardware, software, and data analysis need to be improved to make it a reliable tool (for studies of fNIRS in the context of presurgical evaluation, see, e.g., Gallagher et al., 2012; Watanabe et al., 1998; Watson et al., 2004).

fNIRS has been used to investigate poststroke aphasic individuals. These studies suggested that neuronal activities in lesioned brain tissue lead to altered changes in cerebral oxygen metabolism and regional cerebral blood flow during task performance. In poststroke patients, language tasks activated areas outside Broca's region. Oxygenation patterns were changed in the sense that there was less increase of oxyhemoglobin and in some studies also less decrease of deoxyhemoglobin (for a summary of language studies in adults see Dieler et al., 2012; Obrig et al., 2010; Quaresima et al., 2012).

Summary

Compared to other neuroimaging techniques such as PET, fMRI, EEG, and MEG, fNIRS still lacks standardization of hardware, software, and data analysis procedures; this lack makes the comparison of studies difficult. Currently, the main problems are the low penetration depth limiting studies to investigate only the surface of the cortex and exclude deep brain structures. Further, only certain parts of the head can be covered with probes thus limiting the regions of analysis.

Most fNIRS studies have shown that language tasks in healthy individuals are accompanied by an increase in oxyhemoglobin and a decrease or no increase in deoxyhemoglobin thus confirming the sensitivity of fNIRS to language tasks. Currently, using fNIRS has been most beneficial in studies on language development with infants and children where other techniques are less suitable. fNIRS seems particularly suitable to investigate language development over time in young children. In aphasic patients abnormal oxygenation patterns were found but more studies are needed to show the advantages of fNIRS compared to other techniques.

As all neuroimaging techniques have their advantages and disadvantages, researchers have started to combine methods to exploit their individual strengths and overcome or minimize disadvantages of one technique. While simultaneous EEG and fMRI recording is already used frequently, combining fNIRS with other techniques such as EEG is still in its infancy. The benefits of such a combination have been reviewed by Wallois et al. (2012).

Brain Stimulation Methods

Applying electrical currents to investigate brain functions or modify the brain in humans has a long history. In 1802 the Italian scientist Giovanni Aldini electrified the brains of decapitated prisoners in public to induce movement in the facial muscles. He observed that left cortical stimulation of the dead brain elicited right-sided muscular contractions (for a historical summary see Harris and Almerigi, 2009; Zago et al., 2008). Toward the end of the nineteenth century, Roberts Bartholow and later Ezio Sciamanna reported the effects of electric stimulation to the exposed brain of two patients: one suffering from an eroding cranial tumor of the skull and the other from a traumatic brain injury. While these experiments on humans raised ethical disapproval in the scientific community, Alberto Alberti received an award for similar work between 1883 and 1884. He performed a series of experiments involving the electrical stimulations of the exposed cortex of an epileptic patient over a period of 8 months. These experiments confirmed the electrical excitability of the cortex in humans and demonstrated somatosensory and motor functions contralateral to the side of stimulation. The next decades saw scientists use the technique intermittently in a variety of settings. Wilder Penfield, the founder of the Montreal Neurological Institute, systematically stimulated the patients' brains with intracerebral electrodes during neurosurgery and associated specific regions of stimulation with motor, sensory, and speech functions. Today intracortical brain stimulation is a routine procedure to establish functional brain maps of patients who are scheduled to undergo surgery mainly for epilepsy with the goal of sparing as much functional brain tissue as possible. Although this is obviously an invasive technique – after all the skull is cut open to expose the brain – the invasiveness in epileptic patients is medically justified. In normal healthy subjects, however, scientists have tried to electrically stimulate the brain through the intact skull using the TMS technique or the tDCS technique.

Transcranial Magnetic Stimulation (TMS)

In 1991, transcranial magnetic stimulation (TMS) was introduced as a tool to study language. Since then the technique has become an integral part in language research and has also been applied in language rehabilitation. Before providing illustrative examples of the use of the technique in language studies, the nature of TMS will be described.

TMS (like tDCS to be discussed below) is a method for noninvasive brain stimulation. It should be noted that 'noninvasive' in this context simply means that the skull is not opened to apply the stimulation. Unlike EEG or MEG, however, which *detect and measure* brain activity, TMS *interferes* with brain function and, in exceptional cases, may provoke seizures. Due to this infrequent complication, TMS is sometimes considered invasive (for example, by ethics committees).

Essential to TMS is a simple coil of wire (encased in plastic) through which an electric current is introduced usually with the help of a capacitor. The coil of wire (often round or in the form of a figure eight) is placed close to the head and area to be stimulated. The rapidly changing current flow in the coil of wire produces a magnetic field oriented orthogonally to the plane of the coil. The field transverses the skin, skull, meninges, and brain fluid without any deviations and induces an oppositely directed electric current in neurons lying parallel to the plane of the coil. The current flow leads to neural depolarization which, in turn, excites or inhibits the cortex thus affecting information processing in the brain (see **Figure 31**).

TMS comes in three varieties. In single-pulse TMS, stimulation is delivered once every few seconds and can be used, for example, to study the relationship between language processes and behavior. In paired-pulse TMS, two TMS pulses are fired very close together in time to see how they interact. Pairing can, for example, provide measures of intracortical facilitation and inhibition during language processing. Finally, in repetitive TMS (rTMS), single pulses are regularly repeated over time. Depending on a variety of physiological effects and degrees of risk, variations are fast or high-frequency rTMS during which more than one magnetic pulse is applied every second (such as 5 Hz, 10 Hz, and 20 Hz). Fast rTMS can induce a transient increase in cortical excitability. With slow or slow-frequency rTMS one magnetic pulse (1 Hz) or less is applied every second and this can induce a decrease in cortical excitability (for a summary see Rossi et al., 2009). rTMS is used, for example, in therapeutic settings to modulate affective (depression) or cognitive functions including language. When planning TMS studies it is important to define the intensity and frequency of the stimulation, train duration, intertrain intervals, and cumulative application (over days, weeks). In addition, to increase precision of the stimulation region, TMS is frequently used with a stereotactic frame and structural MRI scans of the participant.

TMS is relatively safe when the safety guidelines are followed (Rossi et al., 2009). Ferromagnetic material (e.g., cardiac pacemaker, metal in the body) may be dangerous and participants need to be carefully questioned. Discomfort such as pain and headaches have been reported in some participants. The most severe adverse event of rTMS is the induction of seizures; their occurrence, however, is very rare and does not increase the risk of seizures in the future (for details see Rossi et al., 2009).

Advantages and Disadvantages. Participants can act as their own controls, that is allowing comparisons before, during, or after stimulation. TMS allows for an examination of the

Figure 31 How does TMS work? Copyright by Boston Globe via gettyimages, costs 222 Euro and can be obtained from: http://www.gettyimages.com/detail/news-photo/an-illustration-published-in-the-boston-globe-on-june-8-news-photo/175697813.

timing of information processing with a temporal resolution of tens of milliseconds and can be combined with other techniques such as PET, fMRI, or EEG. Limitations of TMS include possible discomfort (headache, pain) and, in rare cases, seizures. TMS only reaches areas at or near the cortical surface. A loud click is heard when TMS is applied, a sensation on the scalp may be felt and muscles may twitch. These may interfere with the experiment and may be particularly disturbing in language studies (for a summary see Watkins and Devlin, 2008).

(For summaries describing the technique of TMS see, for example, Devlin and Watkins, 2007; Rossi et al., 2009; Rossini et al., 2010; Watkins and Devlin, 2008).

TMS in Language Studies with Healthy Individuals

For many years the Wada procedure, that is selectively anesthetizing one hemisphere has been the gold standard to determine on which side of the brain language is predominantly represented. Several studies have investigated the possibility of using TMS to replace the Wada test by, for example, using rTMS in an attempt to inhibit language output in the hemisphere that is dominant. Although some studies have reported promising results, other studies could not replicate the findings.

Lexical retrieval processes have also been investigated with TMS. Imaging studies have suggested that left posterior brain regions (more specifically the left posterior inferior-temporal cortex) are implicated in picture naming. Most rTMS studies have shown increased picture-naming latencies and thus support this view. There are, however, studies that reported *decreased* naming latencies with rTMS over Wernicke's area, and still others have reported faster reaction time on a word-picture verification task – regardless of where (out of five sites) stimulation was applied. Interpretation of these findings is thus difficult (for a summary see Watkins and Devlin, 2008).

TMS studies have supported and extended the insight from other neuroimaging techniques that the left inferior frontal brain regions are involved in semantic and phonological processing. TMS showed that the posterior left inferior frontal gyrus is necessary for phonological processing while the anterior left inferior frontal gyrus is necessary for semantic processing (Watkins and Devlin, 2008).

As early as the 1980s, some theories suggested that understanding speech involves sensory and motor representations. Studies using TMS indicate that speech perception and speech production are closely linked and that Broca's area seems to be the mediator between the two.

Another question that has been addressed is whether motor areas are involved in the neural representation of actions as, for example, expressed in verbs. Some studies have shown a decrease in response times during lexical decisions on action verbs (e.g., *folding arms*) when the motor cortex was stimulated with TMS. Interpretation of these results is, however, complex as one needs to tease apart general activation of the motor cortex and specific effects inherent in action verbs. Other findings are equally difficult to interpret. One TMS study associated a region anterior to the motor region (that is, the left dorso-lateral prefrontal cortex) with action verbs whereas another found it to be implicated in the processing of grammatical categories (for a discussion of these studies see Watkins and Devlin, 2008). (For summaries on the use of TMS in studies of language see, for example, Devlin and Watkins, 2007; Flöel, 2011; Naeser et al., 2012; Martin et al., 2009; Schlaug et al., 2011; Watkins and Devlin, 2008).

TMS in Language Rehabilitation

In patient populations TMS and tDCS (see next section) have been used to enhance the recovery process. The idea is based on studies investigating the motor system. Models of motor recovery after stroke assume that there is rivalry between the intact and nonintact hemisphere. For example, if the left hemisphere is lesioned, studies have shown that there is increased inhibition and thus reduced output in the motor regions of the lesioned hemisphere. This seems to go hand-in-hand with a disinhibition in the same regions of the nonlesioned (in this case right) hemisphere resulting in an imbalance in the interaction of the two hemispheres (for a summary and details see Schlaug et al., 2011). Balance may be achieved by either increasing excitation in cortical regions of the lesioned hemisphere, by decreasing excitation in regions of the nonlesioned hemisphere, or by a mixture of the two. Although the model may be somewhat simplistic, it has received some support from studies with stroke patients whose motor systems were impaired. A similar model has been used to explain favorable and unfavorable recovery in individuals with an impaired language system such as stroke patients with aphasia whose left hemisphere is lesioned (see **Figure 32**). It is assumed that the lesioned left hemisphere is inhibited thus reducing output whereas the intact right hemisphere is disinhibited and overexcited. This is where noninvasive brain stimulation methods such as TMS or tDCS come in. The idea is – in simple terms – to use cortical stimulation to decrease the inhibition of the left hemisphere and make it more excitable, or to decrease the over-excitability of the right hemisphere.

The model is supported by functional neuroimaging studies with aphasia patients who have frequently shown an increased activation in right hemisphere language homologs. These observations have led some researchers to apply slow rTMS over the right hemisphere of chronic aphasic individuals. According to the model this should decrease the activity of the overly excited right hemisphere and facilitate the task. Indeed, studies showed an improvement in naming accuracy and reaction times. If rTMS was performed daily for 2 weeks, this improvement lasted for at least 2 months (Naeser et al., 2005, 2012). Efforts have also been made to combine TMS with speech therapy to enhance the recovery process and additional improvement beyond TMS alone has been shown. Generally, most studies have reported beneficial effects to some degree when delivering rTMS to chronic aphasia patients with or without combined therapy that lasted well beyond the stimulation. There are, however, some studies, that reported that right hemisphere stimulation interfered negatively with performance as did left hemisphere stimulation (for a summary see Naeser et al., 2012; Watkins and Devlin, 2008). Another well-controlled study only found significant improvements when comparing real rTMS with sham applications in severe but not moderate aphasic individuals (Seniow et al., 2013).

Figure 32 Differing accounts of plasticity in language systems in chronic aphasia. (a) After unilateral left hemisphere stroke (gray), some language functions may be subserved by recovered lesional areas or recruited perilesional areas (light green). (b) Right perisylvian areas (light green) may be recruited to subserve some language functions, a process facilitated by decreased transcallosal inhibition of the right hemisphere by the damaged left hemisphere. (c) By contrast, right hemisphere activity may be deleterious. Released from interhemispheric inhibition, right hemisphere structures (red) may exert increased inhibitory influence on left perisylvian areas, impeding functional recovery of lesional and perilesional areas in the left hemisphere (dark green). Figure and legend taken from Hamilton, R.H., Chrysikou, E.G., Coslett, B., 2011. Mechanisms of aphasia recovery after stroke and the role of noninvasive brain stimulation. Brain and Language 118 (1–2), 40–50 (Figure 2, p. 43).

The inconsistent findings may be due to the different types of stimulation and protocols used and the individual patients investigated. Most studies up to now have not been well controlled and have been based on small sample sizes. We do not know the pathological characteristics of patients that may predict success under these procedures. Better controlled studies with larger patient samples and common stimulation standards (as recently suggested by Naeser et al., 2012) are necessary to clarify the findings and the role each hemisphere plays in the recovery process.

Transcranial Direct Current Stimulation (tDCS)

With the knowledge gained from neuroimaging and mapping techniques, and particularly from TMS studies, in recent years tDCS has experienced a resurgence in the clinical and academic world and, due to its simple set-up, has also raised the interest of laypeople (websites such as *tDCS DIY* – do it yourself – bear witness).

A weak direct current is applied most frequently via two electrodes attached to the scalp. The current transverses the skull and creates an electric field in brain tissue leading to voltage changes across the neuronal membranes thus changing neuronal activity and modulating human cerebral cortical function. Depending on the polarity of the stimulation, tDCS results in depolarization of the resting membrane potential thus increasing neuronal excitability (anodal tDCS) or in hyperpolarization and decreasing neuron excitability (cathodal tDCS) (for a summary see Nitsche and Paulus, 2001; Nitsche et al., 2008). tDCS generally produces diffuse (and not focal) cortical stimulation. Size, polarity, and position of the electrodes as well as the applied current intensity and the properties of the tissue influence the strength of the current density in the cortex (Dmochowski et al.; Utz et al., 2010). Depending on the duration and intensity of the stimulation, changes in neuronal activity have been observed not only during but also after the stimulation has ended. The long-lasting aftereffect has been explained by various mechanisms such as the induction of long-term potentiation and depression, an effect on neurotransmitters or a change of local pH, blood flow, brain oxygenation, or calcium neuronal influx (Holland and Crinion, 2012; Monti et al., 2013).

Advantages and Disadvantages. Compared to TMS, tDCS is less expensive, easier to use, more portable, and does not produce noise or muscle twitching thus making fake or placebo trials more reliable. Whereas TMS induces neuronal action potentials, tDCS does not do so as it lacks the rapid depolarization required for the production of action potentials. TMS is both neurostimulatory and neuromodulatory while tDCS seems to be neuromodulatory only (Fregni and Pascual-Leone, 2007). tDCS is considered safe and without serious adverse effects if the safety standards are maintained. If the threshold for current and the charge density are exceeded, brain lesions will result (Utz et al., 2010). It is also important to note that certain medications modulate the effects of tDCS. Finally, it is difficult to determine exactly which brain region is stimulated with tDCS.

Application in Language Research and Language Rehabilitation

tDSC has been used in a wide range of applications in clinical and nonclinical studies investigating motor, sensory, mood, and cognitive functions (for a summary see Utz et al., 2010). In nonclinical language research tDCS has shown effects on word generation and retrieval and verbal learning. In clinical settings, tDCS has been applied to improve language performance in patients with aphasia.

tDCS in healthy individuals. Applying tDCS in a single session in healthy individuals has been shown to influence lexical retrieval processes. These processes are often tested with verbal fluency tasks or naming tasks. Verbal fluency tests have been used as a measure of phonemic fluency (generating words in response to a letter cue-word such as 'F') or as a measure of retrieval from semantic memory (generating words that belong to a particular semantic category, such as animals). Applying anodal tDCS over the left prefrontal cortex during verbal fluency tasks and over the left dorsolateral prefrontal cortex during naming tasks improved the performance on such tasks while cathodal or sham (fake) tDCS did not show any effect (for summaries see Cattaneo et al., 2011; Fertonani et al., 2010; Holland and Crinion, 2012; Iyer et al., 2005).

For example, when individuals named the pictures they saw on a screen while their left inferior frontal cortex (Broca's region) was being stimulated, their response time decreased compared to the nonstimulation (Holland et al., 2011). When participants were engaged in learning an artificial grammar, stimulation of the same region facilitated the detection of syntactic violations (de Vries et al., 2009). Instead of naming objects, in still another study, individuals had to name famous people. This time tDCS was applied over the right anterior temporal lobe and this led to improved accuracy in naming famous people (Ross et al., 2010).

tDSC has also been shown to have an effect on verbal acquisition and learning. Cathodal tDCS over the left motor cortex produced a negative effect on vocabulary acquisition while anodal or sham (i.e., fake) stimulation had no effect (Liuzzi et al., 2010). Learning speed and accuracy during the acquisition of new words increased when anodal tDCS was applied over Wernicke's area (Flöel et al., 2008; Valentina Fiori et al., 2010). Word learning over 5 days improved with tDCS and the learned material could still be retrieved a week later (Meinzer et al., in press).

tDCS in aphasic individuals. Compared to studies with healthy individuals, the number of studies with aphasic individuals is still rather limited. Applying tDCS to regions in the affected left hemisphere in individuals with fluent or nonfluent aphasia during naming tasks showed some improvement either in naming accuracy or exhibited an effect in the reaction time for trained items (Fiori et al., 2013; for summaries see Hamilton et al., 2011; Holland and Crinion, 2012; Schlaug et al., 2011). One study found naming improvement in only one out of several patients (Volpato et al., 2013). Another study applied anodal tDCS to the temporo-parietal junction of the intact right hemisphere of a chronic aphasic patient and reported positive effects in a naming task up to 2 weeks after the stimulation (Flöel, 2011). Multisession application of tDCS and stimulation of the left hemisphere (the site of stimulation varied in the studies) also showed naming improvement that lasted beyond the duration of the session (see Holland and Crinion, 2012, for a summary).

In sum, current evidence shows that tDCS induces an effect on word generation and retrieval and lexical learning in healthy individuals. The effect seems to differ depending on the region of application and on which language function is under consideration. As there are currently no methodological standards defined for tDCS, it is difficult to compare studies. Methodological details are not always reported, and the methods used differ, for example, in the duration and intensity of stimulation, in electrode size and placement, and in various other parameters used in the study protocol. In addition to the limited number of language studies, most extant studies have only investigated small populations of subjects. The number of studies investigating the application of tDSC in aphasia rehabilitation is still very limited and in its early stages. Although most studies report some effect, the findings are not consistent. The limitations mentioned previously also apply here. In addition, questions such as where to stimulate, when to stimulate, and how long to stimulate are even more pertinent in a rehabilitation context. For healthy and pathological populations, more systematic studies are needed with common methodological standards and larger subject pools to clarify the effect of tDCS on various aspects of language.

Summary Noninvasive Brain Stimulation

As methods of stimulation, TMS and tDCS have certain obvious advantages in neurolinguistic research over the purely passive observational methods mentioned in previous sections. By employing TMS and tDCS, neural circuits associated with language understanding and production can be both inhibited and facilitated. tDCS is valuable for its ability to induce not only motor functions but to accelerate some elements of language processing. TMS allows for the testing of causality in selected areas of the brain that neuroimaging methods have shown to be important in linguistic phenomena. The therapeutic possibilities of both TMS and tDCS in patients suffering from brain lesions involving language-related areas of the cerebral cortex are currently being explored.

Disadvantages of the brain stimulation methods include their applicability only to sites on or near the surface of the brain. Another disadvantage is the fact that the areas of stimulation accessible for TMS and tDCS are relatively large (centimeters) and at the present time, selective stimulation of discrete brain regions of interest is impossible.

Inasmuch as these methods are relatively new and have been carried out by many independent research groups, there is also at the present time a lack of standardization of the stimulation parameters used in TMS and tDCS.

Outlook

Each technique discussed above has its own weakness and its strength. Further development of hardware and software tools as well as the combination of techniques will diminish the limitations inherent in each individual method. Those techniques that provide the best combination of temporal and spatial resolution and are most cost efficient and portable will probably be those of the future. Taking the hardware out of the laboratory, applying it to 'real life situations' and linking it to modern communication tools might change the approach to the study of language in all its facets and will also have an impact on language rehabilitation. Attempts in this direction in cognitive domains are already under way. Despite all the technological advances, however, it should not be forgotten that 'classical' observational and behavioral techniques cannot always be replaced by even the most advanced technology. And, as mentioned in the introduction, all techniques are in some way limited by their own physical properties, by the physiology of the brain, and by those who try to make sense of both.

This article is reproduced from the previous edition, volume 9, pp. 5822–5828, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

Most statistical analyses involve one or more observations taken on each of a number of individuals in a sample, with the aim of making inferences about the general population from which the sample is drawn. In an increasing number of fields, these observations are curves or images. Curves and images are examples of functions, since an observed intensity is available at each point on a line segment, a portion of a plane, or a volume. For this reason, we call observed curves and images 'functional data,' and statistical methods for analyzing such data are described by the term 'functional data analysis.' It is the smoothness of the processes generating functional data that differentiates this type of data from more classical multivariate observations. This smoothness means that we can work with the information in the derivatives of functions or images. This article includes several illustrative examples.

Most statistical analyses involve one or more observations taken on each of a number of individuals in a sample, with the aim of making inferences about the general population from which the sample is drawn. In an increasing number of fields, these observations are curves or images. Curves and images are examples of functions, since an observed intensity is available at each point on a line segment, a portion of a plane, or a volume. For this reason, we call observed curves and images 'functional data,' and statistical methods for analyzing such data are described by the term 'functional data analysis' (FDA), coined by Ramsay and Dalzell (1991). Though the individual methods and techniques are important, FDA is also a general way of thinking, where the basic unit of information is the entire observed function rather than a string of numbers. A few illustrations will be offered in this article, but Ramsay and Silverman (1997) may be consulted for many more examples and methods, for consideration of the underlying philosophy, and for further references to the literature.

The goals of FDA are essentially the same as for other branches of statistics, and include the following:

1. to represent and transform the data in ways that aid further analysis,
2. to display the data so as to highlight various characteristics,
3. to study important sources of pattern and variation among the data, and
4. to explain variation in an outcome or dependent variable by using input or independent variable information.

We shall illustrate the nature of functional data, these goals, and FDA tools available or under development, through a series of examples.

Human Growth Data: Looking at Velocity and Acceleration

Figure 1 shows the growth patterns of 10 Swiss boys involved in the Zurich Longitudinal Growth Study (Falkner, 1960). Each boy's height is measured at 29 separate ages, but it is more instructive to think of this as a sample of 10 growth curves or functions than as a set of 290 numerical observations. Of particular interest in the study of growth is the way that growth speeds up and slows down at various stages of development, and this is much better illustrated by studying the velocity and acceleration of height. Figure 2 gives estimates of the acceleration or second derivative of these 10 height functions, and shows that around puberty there is a strong pulse of acceleration in growth, followed by sharp deceleration. This is the pubertal growth spurt (PGS), and there is also often a smaller spurt, hardly visible in Figure 1 but obvious in Figure 2, at around age 6.

The Mean Function and the Registration Problem

How would one estimate an overall acceleration curve to quantify the size of these spurts? The dashed curve in Figure 2 is the average acceleration over the sample at each time point, but the PGS for this average is smaller in size and longer in duration

Figure 1 The heights of 10 Swiss boys measured at 29 ages. Notes: Points indicate unequally spaced ages of measurement; solid line is a function fitted to these data by monotone smoothing.

Figure 2 The estimated accelerations of height for 10 Swiss boys. Notes: Heavy dashed line is cross-sectional mean. This is a rather poor summary of the curves because of the presence of the timing of the pubertal growth spurt, called phase variation.

than that of any of the individual spurts. Averages are supposed to look like typical observations; so what went wrong?

The problem is that the curves vary in two ways, termed amplitude variation and phase variation. Alternatively, these are called vertical and horizontal variation, respectively, since amplitude concerns the height of a function at a given point, and phase the location in time of a feature such as an acceleration peak. In short, the actual acceleration peaks in the PGS vary in both size and timing. An artificial example demonstrating these two sorts of variation is presented in **Figure 3**. The phase shift displayed in this figure is constant across the timescale, but many data sets require more complicated and nonlinear transformations of the time axis in order to align curve features like the peaks and valleys in **Figure 3**. The presence of phase variation arises in FDA because many processes involve a system time, or in this case biological time, that does not unfold at the same rate as clock time. In this case, the biological clock of each boy marks off time at its own unique rate.

Figure 3 Panel (a): three height acceleration curves varying only in amplitude; Panel (b): three curves varying only in phase.

A key part of the FDA methodology is time-warping or registration of the data curves to align specific features or to minimize variability, since estimating the mean and most other analyses are thrown off by the presence of phase variation. The time-warping functions may be simple constants, linear functions, or more complicated, nonlinear functions. The amount or shape of warp may be of great interest (see Ramsay and Silverman, 1997: Chapters 5 and 8). **Figure 4** shows time-warping functions and registered height acceleration curves for the growth curves of **Figure 1** estimated using a method developed by Ramsay and Li (1998). The time-warping curve for each individual shows his maturation pattern. A warping function consistently above the diagonal dashed line implies that clock time lags behind development, and therefore development is late in clock terms. If height is measured relative to biological age, the curves in **Figure 2** are aligned as shown in **Figure 5**. Differences in height acceleration after registration correspond to pure amplitude variation in growth

Figure 4 Time-warping functions taking chronological age on the horizontal axis into biological age on the vertical axis.

Figure 5 The height acceleration curves in **Figure 2** aligned or registered by measuring height with respect to the biological time shown in **Figure 4**. Notes: Heavy dashed line is the mean acceleration. This provides a much better summary of the actual curves than **Figure 2**.

patterns. The mean of the registered curves in Figure 5 is a much better summary than the mean of the unregistered data in Figure 1.

The Nondurable Goods Index and More Derivatives

Valuable information may be gained by plotting one derivative of a functional observation against another, a technique called phase/plane plotting. The US index of nondurable goods production is an important economic indicator, and considerable insight may be gained by plotting the acceleration of this index against its rate of increase. If the index had a smooth trend plus a sinusoidal seasonal variation, this plot would be approximately circular with suitable choice of scales. The typical year 1970 in Figure 6 has three main cycles, of which the spring cycle is rather smaller than the summer and fall/winter cycles. Comparisons of plots for different years is instructive. During the stable period 1964–66, there is little year-to-year change, but the period 1973–75 in Figure 6 shows considerable instability, due primarily to the end of the Vietnam War. A typical plot for a more recent year, 1994, shows that the whole pattern has changed, indicating structural changes in the methods and economics of production. For further details, see Ramsay and Ramsey (2002).

Functional Principal Components Analysis

Many FDA methods are adaptations of classical multivariate methods such as principal components analysis (PCA), linear modeling, and analysis of variance (see also Linear Hypothesis; Multivariate Analysis: Discrete Variables, Overview). Functional PCA demonstrates the way in which a set of functional data varies from its mean, and, in terms of these modes of variability, quantifies the discrepancy from the mean of each individual functional datum. Figure 7 (Figure 6.2 in Ramsay and Silverman, 1997) shows the first four principal component weight curves for temperature records for 35 Canadian weather stations. The first mode of variability is overall temperature, but with larger effects in the winter; the second corresponds to variation in annual range of temperature; the third partly to a time-shift of the overall cycle, and the fourth to short, hot summers and long, mild winters, or vice versa. Individual weather stations can then be characterized according to their scores on these four criteria. The interpretability of the components can often be improved by a suitable rotation of the original principal components; see Ramsay and Silverman (1997: Chapter 6).

A Functional Linear Model and Regularization

An example of functional linear modeling is provided by the study of the dependence of the acceleration of the lower lip (lipacc) in speech on neural activity, as measured by electromyographical (EMG) recording. It is reasonable to suppose that the neural activity at time s continues to affect lip movement for only a short period of time, which we denote by δ and this leads to a model of the form

$$\text{lipacc}(t) = \alpha(t) + \int_{t-\delta}^{t} \text{EMG}(s)\beta(s,t) + \varepsilon(t)$$
